E. N——, aged twenty-four, was admitted into Guy's Hospital on March 7th of this year under my care. She had been married fifteen months, and had had one miscarriage before the third month, in June, 1884. Before marriage she was a servant, but since she has done only her own housework. She had never previously had any fit nor was there any tendency to fits in her relatives. Her father died of phthisis. Her own health has always been good. Her menstrual periods have been irregular, occurring at intervals varying from three weeks to two months. She is not quite sure when her last period occurred, but thinks it was in August, 1884, and believes herself to be seven months' pregnant. A week ago she began to have headache, which grew worse and occasionally she vomited. At 1 A.M. to-day (March 7th) she had a fit which lasted a few minutes, and after this at intervals of less than a quarter of an hour she continued to have fits throughout the day, each lasting from three to ten minutes. Ice-bags were applied to the head, and a purgative given which acted. No urine passed during the day. Dr. Faraker, who was attending the case, sent her up to Guy's, where she was admitted at 9.20 P.M. The face was much swollen, and the body and lower extremities œdematous, and some blood was issuing from the mouth, the tongue being severely bitten on the left side. A catheter was passed, but only a drop of urine came away in it. Vaginal examination appeared to bring on the fits. A gag was placed in the mouth to protect the tongue. There was much lividity. Two fits took place in the first half hour, the first being very severe, convulsing the whole body. Chloroform was administered, and it relieved the severity of the convulsions. A catheter was again passed, but no urine came away. At 10.5 P.M. a fourth fit came on during a vaginal examination. The fœtal heart was heard beating at the rate of 140 per minute. The patient has been quite unconscious since morning. At 11.30 P.M. a third of a grain of hydrochlorate of pilocarpine was injected subcutaneously, the patient being well wrapped up in hot blankets. In five minutes profuse sweating took place. At 12.10 A.M. (March 8th) another but much slighter fit came on. 2.15 A.M.: The sweating is nearly finished. She can be roused to some extent, but does not answer questions. A fourth of a grain of pilocarpine was injected, the patient resisting the puncture. Sweating began again in less than five minutes. Much of the lividity has disappeared. Temperature 101°; pulse 120, and less tense than it was. During the night the patient took some milk and brandy. She remained somewhat lethargic and did not speak in answer to questions, but put her tongue out when requested to do so. The left side of the tongue was bitten right through. At noon, and again at 5 P.M., a fourth of a grain of hydrochlorate of pilocarpine was injected hypodermically. Temperature normal; pulse 82. Five ounces of urine were drawn off; specific gravity 1020, acid, highly albuminous (nearly solid on boiling).—9th: No fits; temperature subnormal; took 23 oz. of milk; the tongue is in a very painful and swollen condition, the patient can scarcely speak for it; she is quite conscious. The mouth was washed out with a lotion of chlorinated soda.—10th: Bowels opened; urine passed normally; still albuminous.—11th: Urine acid; specific gravity 1015; albuminous.—12th: Passed 45 oz. of urine during the last twenty-four hours; less albumen.—13th: Colostrum in breasts. Fœtal heart sounds cannot be heard. Uterus seen to contract firmly at times; os patulous.—14th: Pain in abdomen; uterine contractions (?). Has complained of headache ever since she could speak.—15th: Albumen in urine is steadily diminishing in quantity. Still taking milk only.—16th: Labour pains set in, and a partly macerated dead fœtus was born at 4 P.M. The placenta was expressed after giving the patient chloroform, as she was too tender in the abdomen to allow it to be done without. Examination of the fœtus showed it to be between the sixth and seventh month. There was no ossific centre in the astragalus. An interesting point about the fœtus was that the testes were completely descended into the scrotum.

It is not necessary to detail the further progress of the case. The patient made a rapid recovery, and left the hospital on March 28th with only a trace of albumen in the urine, a slight headache, and no œdema. She has been attending as an out-patient under my care since, and the last time she came up there was no albumen at all, and the headache had entirely disappeared. This is the only case that I have treated with pilocarpine, but the result was so immediate and so satisfactory that I thought it worth publishing. The patient had only one slight fit after the pilocarpine was commenced, and she seemed to improve rapidly. How it acted is less clear, but it seemed to me to relieve the system by causing the skin to take on the function of the kidneys vicariously.

Many believe that when convulsions come on during pregnancy the uterus should be emptied as speedily as possible. Others believe in venesection or anæsthetics, especially ether and chloroform. An interesting point in the present case is that the patient was relieved, and practically cured, of the convulsions without emptying the uterus. Labour did set in, however, a week later, apparently spontaneously. It may be that the fœtus died in utero during the convulsions, and that labour set in consequently; but pilocarpine has been used for the induction of labour by Marsman of St. Petersburg and Clay of Birmingham.[1] Hence it may be that the injection of this drug set up the uterine contractions, which resulted in premature birth. Dr. Fordyce Barker in 1879 condemned the use of pilocarpine in puerperal convulsions,[2] asserting that it produced continuous and exhausting depression. In Clay's case there was very alarming depression; but this was a case not of convulsions, but contraction of the pelvis, in which the drug was given to induce labour. In my own case there was no depression to cause any anxiety. Hence I think the drug deserves further trial in these very distressing and often fatal cases.

St. Thomas's-street, S.E.

A COCAINE SPRAY PRODUCER.

By H. PERCY DUNN, F.R.C.S.,

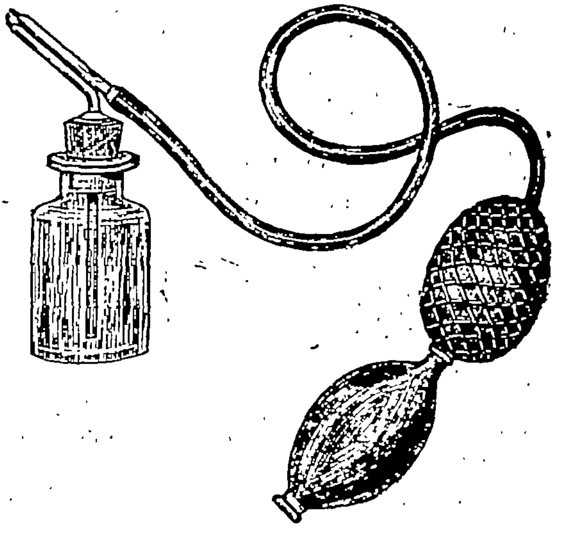
ASSISTANT OPHTHALMIC SURGEON AND PATHOLOGIST TO THE WEST LONDON HOSPITAL, AND LECTURER ON ELEMENTARY PHYSIOLOGY AT THE WEST LONDON HOSPITAL PREPARATORY SCHOOL OF MEDICINE.

As the use of a spray producer undoubtedly commends itself in regard to the employment of cocaine in surgery, I have just devised an apparatus which, by the introduction of certain modifications upon the usual type, will be found to meet the requirements of the case in question.

In the first place, cocaine is a drug the universal use of which is somewhat curtailed by its expensive nature, consequently every drop of a cocaine solution has some significant value; further, the mission, so to speak, of cocaine when applied to a part is eminently a pacific one, and is in all respects different from the germ devastating, germ murdering objects of the gross carbolic spray, which with this purpose in view can be discharged over a wound with no inconsiderable velocity. Having therefore prefaced the description of the new spray producer by these remarks, the significance of the points to which I will now draw attention will be the more readily understood. From the accompanying illustration will be gathered the general appearance of the apparatus, and it is therefore only necessary to refer to its special features.

The spray producer is made of silver, and the jet is as fine as it has been possible to produce; it plays softly over a part without spluttering, and is so constructed as to act upon the eyeball without inconvenience to the patient; in the ordinary sprays the air contained in the reservoirs has only one means of exit—namely, through the jet. One of the results of this is the waste of some of the solution, inasmuch as the spray continues to act until the air is exhausted in the reservoir. In order to counteract the waste, which in the case of cocaine would represent something in the end worth saving, a small aperture has been made in the air-tube which while the spray is in use can be kept covered by the thumb. As soon, however, as the spray is no longer required the thumb is removed, the air at once escapes through the opening, and simultaneously the action of the jet is arrested. This contrivance obviates all dropping of the solution, and at the same time renders the spray exceedingly handy in the matter of regulating its action.

The cocaine spray has proved useful in all ophthalmic operations, and for all operations upon mucous membranes. In the removal of hæmorrhoids, for instance, the assistant could keep the part in an anæsthetic condition by an occasional spray while the surgeon without interruption carried out the various details of the operation. Again, in general surgery it might be equally useful; for instance, in herniotomy, ligature of arteries, and other operations of this nature. The difficulty, however, is to obviate the pain of the first incision through the skin; but this having been overcome or ignored, a sufficiently strong solution of cocaine sprayed over the exposed surface of the subcutaneous tissue would render the operation painless throughout the rest of its course, and for this reason practicable without the employment of a general anæsthetic.



The spray producer can be procured of Messrs. C. Wright and Co., 108, New Bond-street, who have made it at my suggestion, and I am glad to be able to take this opportunity of thanking them for their assistance and for the trouble they have taken in the matter.

St. Stephen's-road, W.

ON A CASE OF IDIOPATHIC TETANUS.

By OCTAVIAN N. ROYLE, M.D., F.R.C.S. Eng.

I was sent for at two o'clock on the morning of March 11th last to see the wife of the gravedigger of the parish of Grouville. The messenger upon inquiry informed me that she had been feeling ill for the last ten days with spasms and slight pains in the stomach, and that her bowels had been unrelieved for more than a week. Looking at the constipation as cause and effect—the night, moreover, a stormy one, and the house some distance from my residence,—I did not consider the nature of the attack one of sufficient urgency to pay a visit at that early hour, so sent her by the bearer a brisk purge of croton oil, with directions to foment the body well until I saw her. Calling at eight o'clock the same morning, the bowels, I found, had freely acted, but the pain and spasm associated therewith had much increased. I then for the first time recognised the nature of her case. The last day in February, it seems, this poor woman had become greatly alarmed at seeing the hand of a child placed on a machine for cutting turnips in motion, although with no injury to the child further than a slight graze of one finger. It was a clear case of idiopathic tetanus from nervous shock. The poor husband was in great grief and distress about his wife, whom I succeeded in calming by my assurance that she would soon be better; nevertheless, every day for more than a week after first seeing her the symptoms increased in severity. Trismus and opisthotonos at one time were well marked, the latter coming on after an interval of some hours, and lasting from five to ten minutes, resisting apparently all treatment employed, first with opium, in two-grain doses every three hours for three consecutive days, then with chloral, in half-drachm doses every four hours for a like period, with very little improvement, and subsequently with one grain of morphia injected hypodermically every night with two of Indian hemp, repeated at short intervals during the day, the symptoms after this treatment gradually disappearing on the second day until her recovery, just three weeks after receiving the shock. The case, I think, of some interest and worthy of record; first, from the great impression made on the nervous system from so slight a cause; again, no marked symptom of the disease showing itself until the eleventh day after the fright, resisting at first all treatment; and lastly, succumbing to Indian hemp and morphia injections, a line of treament I should commence with most certainly if ever called upon to treat a similar case.

UNIVERSITY COLLEGE HOSPITAL.

RENAL CALCULUS; NEPHRO-LITHOTOMY; CURE; REMARKS.

(Under the care of Mr. BERKELEY HILL.)

THE treatment of calculus of the kidney is well illustrated by the two cases which we publish this week. In the first case, where the symptoms had been noticed about seven months before operation, the renal structure had been so little altered by inflammatory changes that the organ was left after removal of the calculus. In the second, symptoms referred to the kidney had been present on and off for sixteen years, and extensive pyonephrosis induced by the presence of the calculus; for this the kidney was also removed. In each the result was satisfactory, and the cases form interesting contributions towards the surgery of the kidney, which has made such rapid advances during the last few years.

For the report of this case we are indebted to Mr. Bilton Pollard, B.S., surgical registrar.

E. R——, a woman aged forty, was admitted to the hospital on Oct. 23th, 1884. She stated that about three months previously she began to suffer from a gnawing pain in her right loin, which shot down to her right groin and knee; the pain came on suddenly, and was attended by vomiting. About a week later her urine was thick and red, but not, *she* thinks, due to blood. She passed urine frequently during both day and night; she never noticed any blood in it.

On admission the patient had occasional attacks of pain in her right groin and thigh; she had some tenderness in the right loin, but it was doubtful if any fulness was present there. Her urine was acid, had a specific gravity of 1020, and contained an abundant deposit of pus. She remained only three days at the hospital at that time, but she was readmitted four months later, and then stated that during the interval the attacks of pain had been more severe. Her urine was acid; it had a specific gravity of 1010, and contained a large quantity of pus, and on one occasion was dark-brown from mixture with blood. There was a slight fulness in the right loin, and during deep inspiration the kidney could be felt, and it was rather tender. From the persistence of the symptoms and absence of others connected with the bladder, Mr. Hill concluded that there was a calculus in the right kidney; and on March 11th, 1885, he exposed the kidney in the loin and punctured it in several places with a needle, but he did not strike a calculus. He next explored the surface of the kidney thoroughly with his finger and detected a hard substance at the lower part of the organ near the hilus; towards this point, guided by the position of the tip of his finger, he passed a knife through the kidney and struck the calculus. Finding it closely embedded in thick layers of fibrous tissue, he then enlarged the incision in the hilus of the kidney, and after freeing the calculus with a scoop, he extracted it with his finger. The wound was closed, except at the posterior part, where the drainage-tube was placed; carbolic gauze dressings were applied. During the first forty-eight hours after the operation the watery fluid, probably serous, not urinous, which drained from the wound was too great for the antiseptic dressings to retain. Notwithstanding this, the wound remained aseptic all through. About eight hours after the operation the patient passed three ounces and a half of urine per urethram; it contained pus. Nine hours later she passed an ounce and three-quarters of urine, which contained much less pus. During the first twenty-four hours after the operation the total amount of urine passed was only twelve ounces, which contained thirty-nine grains of urea; during the next twenty-four hours twenty-seven ounces of urine, containing 106 grains of urea, were passed. The quantity of urine excreted increased day by day until it reached forty-nine ounces, containing 364 grains of urea, during the sixth period of twenty-four hours. On the fourth day after the operation the pus entirely disappeared from the urine and remained absent for about six weeks, and then returned in slight amount. The patient had no return of the lumbar pain. She was discharged seven weeks after the operation; there was then a little pus in the urine, and the wound in the loin was almost healed. The calculus weighed 142 grains; it had an irregularly conical shape, and measured an inch across its base and along the two longest sides; the apex of the cone was smoothed off, and was represented by a flat facet, which seemed to indicate that it lay in the kidney against another calculus, but although this was carefully searched for at the time of the operation, it could not be detected. The patient was seen again on May 15th, when she was in generally good health. She said that she had felt pain in her right loin during that day for the first time; the wound had healed, and there was no fulness or tenderness there; her urine was turbid with flocculent pus.

Remarks by Mr. BERKELEY HILL.—The above case of nephro-lithotomy was very successful, though disappointing. It was successful in that a correct diagnosis of a renal calculus could be made on the presence of three symptoms—persistent pain in the loin, shooting thence towards the groin, the presence of pus in acid urine, and occasional slight hæmaturia at the onset of the case; successful also in that the calculus was found and removed without difficulty through an incision into a healthy kidney from the loin, with the effect of removing the symptoms from which the patient suffered. But the case is also disappointing in that after the urine had been free from pus for six weeks, and the pain in the loin relieved, there should be a return of the purulent discharge. It is difficult to explain this relapse, unless we conclude that there is still another calculus in the kidney, and this view is somewhat supported by the existence of a flattened surface on the irregularly shaped calculus which was removed. This flattened surface was observed at the time of the operation, and I searched very carefully for another calculus, but failed to detect one, and attributed the surface to the stone having been moulded in a calyx which fitted it closely. It is possible that so long as the wound in the loin remained open the pus discharged itself through that channel, and that when the wound closed the pus was obliged to find a vent along the ureter. Meanwhile the patient is enjoying a state of health and complete freedom from pain which she has not had for some years past.

DUNEDIN HOSPITAL, NEW ZEALAND.

A CASE OF NEPHRECTOMY FOR CALCULOUS PYELITIS AND PYONEPHROSIS; CURE; REMARKS.

(Under the care of Dr. COLQUHOUN.)

THE notes of the following case are furnished by Mr. Christie, clinical clerk.

John C——, aged forty-four years, a shepherd, single, was admitted on Dec. 26th, 1884. He is a native of Inverness, Scotland, but had been in Otago for the last twenty years He came of a healthy family, and, excepting his urinary troubles, had always been a healthy man. About sixteen years ago he first felt pain in the left side, just below the ribs behind, and shooting towards the front. His urine was dark in colour and contained blood. These symptoms continued for about a year. He was then bled and took some medicine, and was free from pain afterwards for about two years. The pain again becoming severe, he came to Dunedin, where a doctor told him that a calculus was passing down from his kidney to his bladder, and after some treatment the pain again ceased. Two years later he began to feel something turning in his bladder, and the urine was frequently suddenly stopped in micturition. Blood was passed occasionally, and he had several attacks of shivering. The urine then began to dribble away in small quantities when he tried to pass it. He came into Dunedin Hospital, and while there Dr. Hulme made an incision into the urethra in front of the membranous portion, and removed a small calculus. He left the hospital well, and was free from any severe pains for four years. He then again had pain in the left side and was "fevered," for which symptoms he was admitted into the Queenstown Hospital, where he stayed for about a week. Since then he has frequently had pain in the left side, worse on riding or after any exertion. His urine has contained a thick sediment for a good many months, he cannot tell exactly how long, and lately he has lost flesh and strength to a considerable extent. In November, 1884, the pain in the left side became severe and continuous, but he does not recollect having any sweating or shivering attacks.

Present condition (Jan. 13th).—The patient is a man of exceptionally good physique, but somewhat emaciated. He says he has lost at least two stone in weight within the last few months, and that he is much weaker than he has ever been. The lungs and heart are healthy. No abdominal tumour can be felt, but on deep pressure in the left hypochondriac region he complains of pain. There is no fulnesss in that region nor any notable increase of dulness. The pulse is quick and somewhat weak. The temperature is normal. He complains of constant dull aching pain in the region of the left kidney. The urine is faintly alkaline, contains phosphates, and there is a deposit of pus on standing to the extent of about a tenth of the total amount of urine. On the 15th there was little or no deposit in the urine examined. On the 18th, at noon, he had a severe and prolonged rigor, the temperature rising to 105°; the urine afterwards passed contained an abundance of pus, and was acid in reaction. For the next few days the temperature kept about 100° to 101°; on the 21st the urine contained no trace of pus, and was free from albumen. The bladder was examined with a sound, but was found to be normal. A consultation was held with the members of the hospital staff, and an exploratory incision in the left lumbar region was recommended, with the view of performing nephrectomy or nephro-lithotomy, according to circumstances. The condition of affairs was explained to the patient, who agreed to the operation. The amount of urine passed daily for five days before the operation was noted, and was as follows: Jan. 25th, 42 oz.; 26th, 35 oz.; 27th, 37 oz.; 28th, 35 oz.; 29th, 33 oz.

On the 24th the temperature was 101·4°, and it kept fluctuating daily, but there were no severe rigors.

Operation (29th).—The patient, being anæsthetised with ether, was placed on his right side with a pillow under his flank. An incision was made on the left side, parallel with the last rib and about an inch below it, extending from its anterior extremity to the outer border of the erector spinæ. The distance between the lower border of the centre of the rib and the crest of the ilium was two inches and a quarter. On cutting through the skin, muscles, and fascia, the lower end of the kidney was laid bare without difficulty. It was elastic and fluctuating, and an aspirating needle was inserted. About six ounces of thick pus were drawn off. The needle was then pushed in various directions, but no calculus could be felt. An incision was made into the kidney, and about eight or ten ounces of pus subsequently escaped. On passing the finger into the opening, the kidney could be felt to be sacculated and much enlarged; externally it was strongly adherent to surrounding parts in every direction. The kidney was with considerable difficulty separated from its attachments, and was pushed from the abdomen towards the wound. The external incision was increased anteriorly, the amount of space to be gained by a downward incision being so small that no attempt was made to increase the aperture in that direction. As it was not possible to withdraw the kidney whole, a stout hempen ligature was passed round the pedicle, and the lower half of the kidney was cut through and taken away. Considerable bleeding followed this, which was controlled by pressure with sponges and forceps. A large calculus could now be felt in the pelvis of the kidney, and two or three small pieces extending into the calyces were removed. The other part of the kidney was then removed, another ligature having been placed on the pedicle, which was drawn towards the edge of the wound. No attempt was made to ligature the ureter and vessels separately. Bleeding ceased after the second ligature. The wound was washed out with chloride of zinc solution, a large drainage-tube was put in, and the skin incision was closed with silver sutures. The operation was done under the spray. The kidney weighed twenty ounces and a quarter, and the calculus half an ounce.

30th.—The patient has passed a good night. To-day he says that the pain in his side is less than it was before the operation. In the twenty-four hours following the operation he passed thirty-five ounces of urine; that first passed contained a great deal of blood and some pus, the last being quite clear. Temperature (10.30 A.M.), 100°; pulse, 112.

31st.—10.30 A.M.: Temperature 103·2°; pulse 120. There is a good deal of oozing of sanious pus from the wound. In twenty-four hours he passed thirty-four ounces of urine, containing a copious deposit of phosphates, but free from pus or albumen. Henceforth no pus or albumen was present in the urine. During the first week the wound became very foul and septic symptoms set in. The tongue became brown and hard, the temperature reached 104·8°, and the pulse was as high as 150. Charcoal poultices were applied, and the wound was freely irrigated with warm carbolic solution (1 in 40). The abdomen remained soft and free from pain. On February 9th the wound was again healthy and clean, the temperature being 99°; from that time convalescence was steady, and healing went on rapidly. The patient was able to get out of bed on February 28th.

On March 20th the ligatures had not yet come away from the pedicle, but with the exception of the small sinus thus left the wound had entirely healed, and the patient was gaining flesh and strength daily. From fifty to fifty-six ounces of urine were passed daily. During the first week, while the wound was septic, a bed-sore formed over the right sacral region, which gave rise to a good deal of trouble and discomfort, but which was healing rapidly.

When examined on April 10th the patient was in excellent health.

Remarks by Dr. Colquhoun.—The diagnosis of this case presented no particular points of difficulty. The previous history of calculus, the absence of cystitis, the occasional acidity of the urine, the appearance and disappearance of pus, and the pain in the region of the left kidney, all indicated that the left kidney was the source of the pus, and that it was probably due to the presence of a calculus. The next question that arose was as to the condition of the right kidney. The absence of albumen, when pus was not present, was considered to be satisfactory on that point, and it was thought to be very probable that the right kidney was, and had been for some time, doing the main part of the work, and that little extra burden would be thrown on it by removing its diseased fellow. The age of the patient made the operation a serious one, considering the mortality that had followed such operations in patients of middle life. Mr. Barker stated at the Congress of 1881 that out of ten cases of nephrectomy for calculus collected by him, seven had died, and all the recoveries had been in patients under twenty-four years of age. In this case, however, the peculiarly good physique of the man, the absence of any constitutional weakness, and a previous life of strict temperance in a healthy climate, made the patient a good subject for operation in spite of his years. An operation under such circumstances certainly seemed more likely to be successful than in many of the cases of nephrectomy for strumous disease performed on unhealthy and cachectic individuals many years younger. The lumbar incision was chosen in preference to the abdominal, and no regret was felt for this, notwithstanding the difficulty experienced in removing the kidney through a comparatively small aperture. The condition of the kidney bore a strong resemblance to that of a phthisical lung strongly bound down by pleuritic adhesions, it was so strongly adherent to all the surrounding tissues; and there would have been considerable danger of some of the fetid pus escaping into the cavity of the abdomen had the incision been made from the front. The treatment after the operation was mainly directed to keeping the wound clean and to maintaining the strength of the patient. He rallied quickly from the shock of the operation. During the few days of septic trouble brandy was freely given. The bowels were somewhat constipated throughout, but this the patient said was not more than was his habit when he was at work. The calculus externally consisted of phosphates, with no trace of uric acid; no examination of its internal composition has yet been made.

GREENOCK INFIRMARY:

PENETRATING WOUND OF ABDOMEN, WITH PROTRUSION OF STOMACH AND INTESTINES; REDUCTION OF HERNIA AFTER ENLARGEMENT OF WOUND; DEATH.

(Under the care of Dr. DOUGLAS.)

THOMAS C——, aged eight, was admitted on April 18th, 1885. This boy, when bathing in a shallow burn, lay down on his belly close to the bank in order to practise swimming movements. The ragged edge of a broken bottle which lay at the bottom of the burn penetrated his abdominal wall. Saying nothing about his injury, he at once got out of the water, walked to his clothes, put on his shirt and one leg of his trousers, but his exertions caused his intestines to protrude through the wound, and this being observed by his companions; assistance was sent for, and he was at once brought to the infirmary in the ambulance van, being admitted about an hour and a half after the accident.

On admission, midway between the umbilicus and the ensiform cartilage, in the median line, was an incised wound only three-quarters of an inch long, through which had protruded the stomach, omentum, and almost the entire length of the jejunum and ileum. These viscera now lay to the right of the middle line. The stomach and intestines were uninjured, although considerably congested and distended with flatus; the peritoneum covering them was smooth and glistening, and no dirt or foreign body of any kind was adherent. The omentum was slightly torn here and there, and at one part a very small portion of it was almost detached. The neck of the hernial protrusion was firmly constricted by the edges of the wound. The surface of the patient's body was cold; his face pale and anxious-looking, and the pulse slow and feeble. Chloroform was administered, the viscera carefully washed with a weak tepid solution of carbolic acid, and the semi-detached portion of the omentum firmly ligatured with carbolised catgut and removed. Careful attempts were then made to return the hernia, but, as was expected, they proved of no avail, so the wound was enlarged upwards and downwards about half an inch in each direction, and the whole protrusion was then returned with comparative ease. The edges of the wound were stitched accurately together with sulpho-chromic gut, a drainage-tube inserted at the lower end, and a dressing of protective carbolic gauze and carbolised wool applied. The carbolic spray was employed during the operation. He was ordered small quantities of brandy and iced milk.

19th.—Slept fairly well during the night; micturated freely; complained of no pain; pulse rapid and feeble. Temperature in rectum 100·8°. The following was ordered: solution of morphia and simple syrup two drachms of each, distilled water two ounces; one drachm every two hours. Incessant vomiting and hiccough began shortly after mid-day; he gradually sank, and died at 9.30 P.M., thirty-two hours after admission.

The wound was reopened and enlarged after death. No hæmorrhage had taken place; no peritonitis; the viscera had exactly the same appearance as before their return into the abdominal cavity. There was no attempt at healing of the wound.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Fatty Tumours.—Lympho-sarcoma of Tongue.

THE last meeting of the session of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. At the close of the meeting the President said that the ventilation of the room in which the Society met would undergo a thorough revolution during the vacation.

Mr. BLAND SUTTON read a paper on Fatty Tumours, the object of which was to endeavour to point out the probable origin of certain forms of fatty tumours which occur in unusual situations. The author removed the biceps cubiti muscle of an old woman, a dissecting-room subject, the upper part of which had become metamorphosed into a lobulated fatty tumour; it was not merely an example of fatty degeneration of a disused muscle, but a genuine lipoma. Mr. Pearce Gould removed a congenital fatty tumour from the clavicle of a child, the base of which contained striated muscle fibre. Mr. Butlin reported a similar case in the twenty-eighth volume of the Pathological Society's Transactions. The patient, a girl seven years old, was operated on by Mr. T. Smith for a fatty tumour growing among the deep muscles of the calf. It contained striated muscle fibre. In a fibro-muscular tumour of the uterus, removed by Sir J. Paget, and reported in the twelfth volume of the same Society's Transactions by Mr. T. Smith, a fatty tumour was found of the size of a pigeon's egg. These four cases seem to favour the view that the muscle-tissue had suffered fatty degeneration, and the retrograded elements had acquired, or assumed, an independence and grown into a tumour. Muscles do not stand alone in this respect. Inflammatory new formations may degenerate into fat and become veritable fatty tumours. Dr. Norman Moore presented to the College of Surgeons Museum a ureter surrounded by a "fatty tumour." The ureter contains a calculus, and in the catalogue is printed the following noteworthy explanation: "The fat was probably produced by fatty degeneration of newly formed fibrous tissue (inflammatory new formation) occasioned by irritation of the calculus." The museum of the Middlesex Hospital contains a specimen illustrating syphilitic stricture of the rectum; the pelvic organs are embedded in a mass of fat, tunnelled with sinuses from the bowel. Possibly the stricture and the passage of fæcal matter outside the bowel had acted as irritants, leading to increased activity in the parts surrounding the gut, which fell just short of inflammation and led to overgrowth of fat, or in the early stage of the stricture inflammatory products were exuded, which later retrograded into fat and took on independent growth. Dr. J. K. Fowler pointed out the condition to the author, and stated that it occurs in many cases of long-standing stricture of the rectum. In November, 1876, Mr. Henry Morris removed from the buttock of a man a fatty tumour containing a shapeless mass of bone. Careful examination of this and similar tumours, particularly a case described in the thirty-third volume of the Pathological Society's Transactions by Mr. F. Treves, lends support to the notion that congenital fatty tumours containing bone are really examples of "parasitic fœtuses whose soft parts have retrograded wholly or partially into fat." The question is also borne out by numerous examples in pathology and comparative anatomy. The fatty contents of dermoid cysts may be explained in the same way—viz., degeneration of the higher tissues of which it was originally composed. The "lipoma arborescens" of Müller doubtless arises by fatty retrogression of the villous processes, which are so common in joints affected with chronic disease. Evidence in many ways is adduced in the paper to prove that any of the soft tissues of the body, normal or pathological, may degenerate into fat, and that this retrograded tissue does, in some instances, assume an autonomy and grow into a veritable fatty tumour. — Mr. BUTLIN said that, working at lipomata of infancy and childhood some years ago, he had come to the conclusion that they might arise as degeneration of fibrous tissue. He thought that Mr. Sutton had extended these views, and with a considerable show of truth.—Dr. CREIGHTON considered that Mr. Sutton had hardly proved his point. He said that the notion that such congenital fatty tumours were parasitic fœtuses was far-fetched. In dermoid cysts no doubt there was a greasy substance; but this was due to the existence of an enormous number of sebaceous glands. Throughout the paper fat was spoken of as degenerate tissue, and Dr. Creighton objected to such a view. The paper did not state where the fat occurred precisely in the tumour of the biceps cubiti muscle, and there was no histological description. He believed that it was just as likely that we had to do with a congenital rudiment of fat in cases of congenital fatty tumour. When fat forms in the intestine, in the tract of an old hernia, he had found that the fatty change proceeded in the most orderly way, and without preceding inflammation.—Mr. BLAND SUTTON, in reply, argued that fœtuses did remain at their autosite, and gave several illustrations: one, that of a rudimentary fœtus on a man aged thirty, in which the fœtus moved its stunted and rudimentary limbs; and another case in which the fœtus was attached to the breast. The fatty material in dermoid cysts was no doubt of two kinds: the one was a fluid sebum; the other was unquestionably fat and a genuine adipose tissue. His paper was simply an earnest endeavour to give some satisfactory explanation as to how fatty tumours may arise in such untoward situations in which we sometimes find them.

Mr. Jonathan Hutchinson read a paper on a case of large Lympho-sarcomatous Tumour of the Tongue. The paper consisted chiefly in the narrative of a case in which a tumour, beginning in early life in the substance of the tongue, had required removal on account of its large size. It had grown until it completely filled the mouth and obstructed deglutition and respiration. It weighed after removal seven ounces, being probably the largest tumour of the tongue on record. The operation necessitated a preliminary tracheotomy and section of the lower jaw at the symphysis, since it was quite impossible to get at the mass from the mouth. The patient was a medical student, aged twenty-two, and the tumour had been growing for twelve years, or possibly much longer; it was painless and of almost stony hardness. Its surface at one part was covered with papillary outgrowths, but there was not the least tendency to ulceration. There was no gland disease. The patient was in good health, and the inconvenience caused by the size of the tumour was the only reason for its removal. Careful microscopic examination had been made by Mr. Eve, Dr. Klein, and others, with the result that the tumour was declared to be of a sarcomatous or lympho-sarcomatous nature. This verdict had unfortunately been supported by the final result, for after about two years of good health, without the slightest symptom of recurrence, a new growth suddenly developed in the scar, and, increasing very rapidly, brought about the patient's death. The author, whilst admitting that the tumour in its final development was of a malignant or sarcomatous character, drew attention to certain clinical features which were different from those common to such growths. If not actually congenital, it had begun in very early life, and its growth had been very slow and absolutely painless. The development of coarse papillæ on its surface, without any tendency to ulcerate or fungate, was another feature of peculiarity. He had not been able to find on record any case which corresponded with his own in all its characters, but had met with several which resembled it in its early stages. In one of these, in which a portrait was shown, the appearances on the surface were exactly similar; but in this no tendency to persistent growth was shown, and the patient, a railway porter, aged twenty-three, is still free from any material inconvenience. This and some other cases led the author to believe that the starting-point had been of the nature of a congenital mole, in which other morbid tendencies had been developed later on. The paper was illustrated by a series of drawings, and by the preparation itself, which had been preserved in the museum of the College of Surgeons.—Dr. Johnson congratulated Mr. Hutchinson on the temporary success which had attended the surgical interference.

Mr. Hutchinson showed a living specimen of Papillary and Nævoid Mole of the Tongue in a railway porter. There was hypertrophy of one-half of the tongue with, in addition, papillary growths all over the organ and enlarged veins. The growth had certainly diminished during the last year or so. — Mr. Butlin had investigated the literature of the subject of sarcoma of the tongue, and so far as he could make out there was but one on record besides that related by Mr. Holmes. He thought that Mr. Hutchinson was probably right in believing that the growth had arisen in some other tissue. It was not an ordinary round-celled sarcoma, and Mr. Hutchinson's view as to the origin must be accepted. He remembered the case of a little girl under the care of Mr. Howard Marsh, in which there was a papillary growth on the tongue and the disease spread through that organ. Certainly Mr. Bryant had shown that such growths might be due to the degeneration of a nævus, for Mr. Bryant saw one case pass through the various stages. If a further proof of the nævoid character were wanted, it would be found in the profuse bleeding, which was with much difficulty controlled in one case operated on by Mr. Butlin. Mr. Hutchinson's case was most probably one of a congenital condition of the tongue which had undergone cystic and papillary degeneration, and in this degenerated tissue a sarcoma had developed. The case was one of surpassing interest.—Mr. Howard Marsh said that he had seen three cases of a nævoid condition of the tongue at the Hospital for Sick Children. In two of these the patients were about three months old. It was interesting to know that such nævi did take on a coarse papillary degeneration.—Mr. Barker had seen one more case than those he had put on record—that of a young woman aged twenty-one, in whom there appeared to be a rather larger admixture of the nævoid condition than existed in Mr. Hutchinson's case. The papillæ appeared to be made up of saccules, which, on incision, gave vent to serous fluid. A lymphangiectatic condition was probably also present in these cases. Injection could be performed from the lymphatics into the veins, and *vice versâ*. Setons had been used, with the result of setting up glossitis; and an incision into the inflamed area did not give rise to much bleeding, though there was a considerable escape of a clear fluid. — Mr. Hutchinson did not accept the limitation of the tumour to the class of nævus only; he considered that there was the "mole" element—that is, a hypertrophy of the various tissues. Mr. Arnott had described enlargement of the lymphatics, as well as all the other tissues, in a case of the kind. He did not think that such cases always began as a nævus. In many cases there was hypertrophy of all the solid tissues.

OPHTHALMOLOGICAL SOCIETY.

Congenital Changes in Vitreous Body.—"Black" Cataract.—Nævoid Conditions of Eyelids and Orbital Tissues.—Intraocular Gumma.—Double Retinal Glioma.

An ordinary meeting of this Society was held on the 4th inst., Mr. H. Power, F.R.C.S., Vice-President, in the chair.

Mr. Lang showed a specimen of Congenital Changes in the Vitreous Humour with choroiditis and atrophy of the optic disc.—Mr. H. Power asked for what reasons the changes were considered to be congenital.—Mr. H. E. Juler suggested that there had been an inflammatory process which had left behind it the fibroid changes; the lesions were not the remains of the hyaloid artery.—Mr. Lang said that the sight of the right eye had always been defective; the left eye was normal. By direct inspection three branches could be seen, one of which passed vertically upwards and another horizontally inwards; he thought it could not be the remains of an artery, and suggested that an intra-uterine inflammation was the cause: there was also choroiditis of extensive nature; the optic disc was decidedly grey, and much darker than in ordinary grey atrophy. In answer to Mr. Power, he said there was no specific history.

Mr. H. Power showed a specimen of "Black" Cataract, which was the only one that had occurred in his own practice. Mr. Myrtle, at the Western Ophthalmic Hospital, had informed him that he had seen three black cataracts in Paris during a period of six months. Mr. Power's case was that of a woman aged forty-three, in whom the field of vision was good in all directions, though feeble. The lens was removed without iridectomy, and the cataract came away in the capsule. The result would in all probability be very good.—Mr. Swanzy had seen many black cataracts both in von Graefe's and his own practice. The result of their extraction was rather unsatisfactory in his experience.—Mr. Lang referred to two cases which had been under his care. In one there was extensive myopia and mixed astigmatism; the patient did well for a time, but subsequently detachments of retina came on and useful vision was destroyed. He had seen another case at Moorfields also in a myopic patient.—Mr. Juler remarked on the large size of the lens in Mr. Power's case, and thought that the eye ought to have been glaucomatous were it not for the myopia.—Mr. Nettleship had seen many cataracts of a brown tint, but none actually black; he referred to Mr. McHardy's case, published in the second volume of the Society's Transactions.—Mr. Mackinlay had seen a few cases of black cataract.—Mr. Adams Frost remarked on the obscure nature of black cataracts.—Mr. Henry Power suggested that absorption of hæmoglobin might account for the colour, and thought a chemical examination might clear up this point.

Mr. McHardy showed a girl with a Subcutaneous Nævoid Condition of the Eyelids, which was attended with alterations in the temporal bones. There was no proptosis; the eyeball appeared to be unaffected.—Mr. Spencer Watson referred to a case of nævus of the orbit, orbital tissues, and upper lid, which did not extend so far into the temporal region as in Mr. McHardy's case. He had used ligatures to tie portions of the growth in the lids and the actual cautery for the orbital portions; by these means he had obtained a good result. He thought Mr. McHardy's case not so favourable for operation, and yet he suggested that some of the vessels might be tied up.—Mr. H. Power had seen many cases of nævus of the eyelids, and referred especially to the case of a child aged between three and four years, in which he had twice used a deep figure-of-8 ligature, with success at the second operation. He mentioned another case in which a nævus was rapidly growing at the inner canthus and caruncle of the eye and had penetrated into the orbit; this was in a female infant aged eight months. He dissected out the growth with some difficulty after separating it from the conjunctiva; there was some hæmorrhage, and the operation had to be more extensive than he had anticipated.—Mr. Nettleship referred to a case of "lymphatic" nævus in a boy, in whom there was defective vision; nothing was done; an attack of spontaneous inflammation led to no improvement. He considered that Mr. McHardy's case was one of nævus; large cords passed through the growth, which were apparently obliterated vessels.—Mr. Jessop referred to the enlarged veins and cords passing apparently into the external jugular veins.—Mr. Waren Tay asked whether the choroid was affected.—Mr. McHardy said that the choroid was probably free; there was some hypermetropia about 2 D. The growth did not dip into the orbit very much, for there was no exophthalmos. He mentioned a case in a boy aged fifteen, in whom proptosis was a marked feature; he thought he should deal first with the isolated mass in the lower lid, and then proceed to remove a portion from the upper eyelid.—Mr. Adams Frost referred to a case on which he had operated, and said that the skin never resumed its natural texture; in this case the tumour went deeply into the orbital tissues.

Mr. Jessop read the report of the Committee on Mr. Benson's case of Growths on the Cornea and Iris. It was found that the nodules on the cornea were chiefly situated external to the posterior elastic lamina. The nodules consisted of round nucleated cells, which stained deeply; in some spots there were signs of disintegration. There was practically no caseation. No giant cells were found anywhere. No reticulated structure and no bacilli were detected. The growths in the inoculated animals had the same characters. This was not a case of tuberculosis, as the above facts showed, and as was further borne out by the fact that there was no evidence of general tuberculosis in rabbits inoculated into the anterior chamber of the eye.—Mr. Swanzy asked the Committee what kind of growth they regarded it as.—Mr. Jessop, in reply, said some form of granuloma, possibly syphilitic.

Mr. Spencer Watson read a paper on a case of Intra-ocular Gumma in a child aged six years, whose history pointed to inherited syphilis. The father was the subject of phthisis. The patient came to the South London Ophthalmic Hospital with a protrusion of the upper and outer quadrant of the sclerotic. This was punctured, and on it, though no pus escaped, a prominent growth of lympho-pus formed. The earlier stages had resembled those of acute onyx with hypopion, but after the formation of the protrusion in the sclerotic the pus in the pupillary area disappeared. Under a course of mercury the protrusion subsided, leaving a pigmented scar in its place, and a shrunken eyeball. All the other symptoms also were ameliorated, and the child's general health improved. The whole case seemed to indicate an intr-ocular syphiloma. At one time the sympathetic irritation of the sound eye threatened danger to it also, but the mercurial course had a good influence, and, as the damaged eye contracted, the fellow eye lost all irritability and the general health correspondingly improved. This form of syphilitic affection of the eye is, according to the author's experience, very uncommon.—Mr. Adams Frost referred to a case of gumma on the anterior surface of the iris which was absorbed under mercurial treatment; the other eye was symmetrically affected.—Dr. Brailey referred to cases of gumma of the choroid which he had seen, none of a large size. He mentioned cases of tubercle, in one of which the sclerotic was perforated and a suppurative panophthalmitis resulted. In a case of glioma with increased tension a tuberculous mass growing from the optic disc was found. He thought there was evidence to show that genuine glioma does shrink.—Mr. Nettleship had not seen intra-ocular gumma in a child, but had seen many in adults, where there was no doubt as to the acquired syphilis. He remembered very well two cases in women with severe secondary syphilis, and each lost one eye. In one the disease led to the formation of a bulging mass in the ciliary region, which tended to perforate and was broken down in the centre. In another case in a lad it was doubtful whether the growth was syphilitic, tubercular, or of some other nature.—Mr. Lang spoke of a case in a man with acquired syphilis; the gumma was situated on the anterior surface of the iris and perforated the sclerotic. In another instance the gumma separated the iris from the sclero-corneal junction and bulged the sclerotic forwards.—Mr. Power said that it was the early age of the patient which was the interest of Mr. Spencer Watson's case. In adults syphilitic affections of the iris were very common, especially at Chatham, where, the Contagious Diseases Acts not being in force, he had seen numerous examples.—Mr. Spencer Watson said that the mother showed no evidence of syphilis till after the birth of the child; and he suggested that the fœtus was primarily affected, and that the mother was infected from the fœtus.

Dr. Brailey described a case of Double Retinal Glioma, which resulted in the shrinking of one eye and the perforation of the anterior part of the opposite eye by a large projecting mass of new growth. He first saw the child, who is still living, in October, 1882, when there appeared at the fundus of the left eye a yellowish-red vascular reflex. The right also showed a greyish reflex, with a few vessels on it. The disease was diagnosed as glioma, the condition being more advanced in the left eye, where it implicated the entire retinal thickness, and of comparatively short duration in the other, where it was apparently confined to the external retinal layers (glioma exophytum). In the diagnosis of glioma Mr. Vernon concurred. The disease progressed slowly for ten months, when the right eye was apparently the seat of an acute suppurative panophthalmitis, during the progress of which the child lay for several days in a state of stupor. Dr. Brock of Tooting, under whose care she was, attributed this condition to meningitis. Two and a half years from the time of her being first seen the tumour perforated the left eye and projected for about three-quarters of an inch as a rounded mass, about half an inch in diameter, from between the lids. There was at present no evidence of any further extension of the disease. Dr. Brailey thought that the points of interest in the case were its long duration, and the fact that an intra-ocular glioma could shrink and become inert. He referred to such a case recorded by Mr. Snell in the Society's Transactions for 1884, to which he had himself appended another; but in neither of these did the shrinking appear to be the result of a suppurative panophthalmitis. Another point of interest was the probable mode of extension of the disease from one eye to the other. He thought that this, in some cases, at all events, was by the optic nerves and chiasma.—Mr. Power had seen but one case of glioma in both eyes; in this case, and against his wish, no operation was performed, and the child died in great misery.—Mr. McHardy spoke of a case of double glioma in which one eye was removed, but the parents refused to have the other touched. The growth at death weighed 8¼ lb., and the child only 24 lb.—Mr. Francis Mason also spoke of a case of double glioma. One eye was removed, and the further growth in the orbit of that side certainly shrank, whilst the glioma of the other eye went on enlarging.—Mr. Adams Frost thought that, as the growth extended along the optic nerves, removal would prove useless in established cases.—Mr. Swanzy spoke of a case of double glioma which had not extended from one eye to the other, but had appeared independently in each eye. He mentioned a case in which the glioma lasted two years before the disease became extra-ocular, and agreed with Dr. Brailey that gliomata were not always rapid in their growth.—Mr. Power thought it would be important to know whether early removal prevented recurrence in other organs.—Mr. Nettleship referred to a case in which he had removed the eye at an early period and no recurrence had taken place after three years, and Mr. Brudenell Carter had put on record a case in which certainly eight years elapsed without recurrence.—Dr. Brailey had seen altogether twenty cases of ordinary glioma, five of which recovered after excision.—Mr. Lang gave an instance showing that growth may occur in the second eye without extension by the optic nerve.—Mr. Waren Tay referred to a case, probably a glioma, in which there had been no recurrence after eight years.

HARVEIAN SOCIETY OF LONDON.

At the meeting on May 7th, the President, Dr. T. Morton, in the chair,

Dr. M. Handfield Jones read the notes of a case of Porro's Operation. The patient, a single woman, aged thirty, had come to him complaining of a lump in her abdomen; about four months previously she had had an acute attack of pelvic pain, following violent exertion, and accompanied with constipation and great frequency of micturition. Since the attack her courses had stopped, constipation had been very troublesome, and the general health had deteriorated. Physical examination revealed the existence of pregnancy, complicated by a large fibroid tumour impacted in the pelvis, and leaving only a small chink between its anterior surface and the symphysis pubis. At the time of labour it had been found possible to dislodge the tumour under an anæsthetic to such a degree that the performance of craniotomy was deemed advisable; this however failing, the abdomen was opened and the child removed by uterine incision. Then the tumour, being freed from adhesions which bound it to the pelvic wall, was raised out of the pelvis and removed with the uterus. The patient rallied well from the operation, but succumbed on the third day from peritonitis.

Dr. De Watteville read a paper on Electrical Diagnosis in Nervous Diseases. After showing some of the recent improvements effected in electro-therapeutic instruments, he spoke of the method of conducting an investigation of the reactions of nerves and muscles. He then dwelt at some length on the phenomena observed in various forms of facial paralysis. Ordinary facial paralysis from "cold" offers three types of intensity; and an accurate prognosis may often be based upon the results of an electrical investigation; and recovery may be predicted within one, two, or six months respectively. He then explained the relationships between the "reaction of degeneration" and the morbid changes in the nerves and muscles; and he pointed out how the latter depended upon an *interference* with the "*trophic*" *influence* of the motor nuclei. The division of paralyses into "cerebral" and "spinal" (Marshall Hall) is of value if, by these terms, we denote the fact that in some the muscles are cut off from the brain influence only; while in the others the spinal (trophic) influence is also cut off. Progressive muscular atrophy, poliomyelitis, and "wrist drop" from lead or from pressure on the musculo-spiral nerve, were briefly alluded to as offering many opportunities for clearing up doubtful points and framing a prognosis by means of an accurate investigation of the behaviour of nerves and muscles to faradism and to galvanism.

ACADEMY OF MEDICINE IN IRELAND.

At a meeting of the Obstetrical Section on March 6th,

Dr. More Madden exhibited Five Uterine Tumours which he had recently removed from patients in the Mater Misericordiæ Hospital, and read a paper on the Treatment of Uterine Fibro-myomata, as exemplified in his own gynæcological hospital practice during the past fifteen years. In this communication the author described fully his method of removing uterine fibromata by enucleation, and also referred to Emmet's operation for the same purpose, as well as to the treatment of uterine tumours by abdominal hysterectomy, myotomy, and oöphorectomy.—Dr. Kidd agreed with Dr. More Madden that the prevailing epidemic of laparotomies needed to be stayed. Capital operations should only be performed when the risk to life was imminent. The treatment required would vary with the size of the tumour—submucous, interstitial, or subserous. If necessary, the first two classes of uterine myomata might be removed by enucleation. The submucous variety caused most trouble and danger to life through accompanying hæmorrhages, but interstitial tumours might grow towards the mucous surface, and so become practically submucous. In the same way these tumours might become subserous. The latter class very seldom gave rise to really threatening symptoms such as alone would justify serious operations being undertaken for their removal. Mere inconvenience and some amount of pain would not justify laparotomy. Serious difficulty in defecation rarely occurred in connexion with these tumours, but micturition might be so difficult as to call for the use of a catheter. He had generally found it possible to relieve such symptoms by lifting the tumour out of the pelvis. He knew many cases in which very large uterine tumours had existed for many years without giving rise to any real danger to life, even though the abdominal and thoracic viscera were much pressed upon and displaced.—Dr. Macan said that everyone would agree that in the absence of proper indications serious operations should not be undertaken. This rule was obvious; but enucleation as an operation he regarded as infinitely more dangerous than laparotomy. Nor did he accept Dr. More Madden's faith in the efficacy of subcutaneous injections of ergotin. Schroeder had laid down very clear rules and indications for the performance of myomotomy. It was called for in the case of a rapidly growing tumour in a young woman, when it gave rise to symptoms from mechanical pressure or excessive bleeding, or when it interfered with the patient's power of earning her bread. Other indications sometimes requiring operative interference were, according to Schroeder, complication with ascites or with pregnancy. Another rarer indication consisted in evidences of sloughing of the tumour. Removal of the ovaries might in many cases be preferable to myomotomy, but Battey's operation was very difficult and sometimes almost impossible in the cases of large tumours. It would be erroneous to say that menopause held out certain prospects of the cessation of the growth of uterine tumours.—Dr. Byrne thought that the dangers of uterine tumours complicating pregnancy had been overrated. He believed with Dr. Kidd that the more serious operations were very seldom required.—The President pointed out that all of the tumours presented by Dr. More Madden except one were intra-uterine and pedunculated. He entirely differed from Dr. Madden in his estimate of the difficulties and dangers of enucleation. More difficult and less successful operations he had never performed. In his experience enucleation was most often left unfinished. He had some time since made up his mind never again to attempt this operation, except upon examining the uterus he found the tumour so circumstanced as to lead him to think that it would come away very easily. Myomotomy he looked on as a very dangerous operation, and not to be undertaken without the clearest indications. Death from pressure or from bleeding was very exceptional in these cases. He had entirely lost faith in subcutaneous injections of ergotin. It could only be of possible use in the case of intramural tumours. He had lately practised incision over the tumour, with subsequent injections of iodised phenol into the cavity of the uterus at fortnightly intervals, with very distinct advantage.—Dr. Purefoy having spoken, Dr. More Madden replied, and the Section adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

At a meeting of the Society on April 23rd,

Mr. Atkin showed microscopical specimens of a Calcified Enchondroma of the Cerebellum which was accidentally discovered during the post-mortem examination of a boy who died of meningitis following otorrhœa.

Mr. F. Woolhouse related particulars of a case of Hysterectomy in which a large uterine fibroid was removed with the body of the uterus and appendages. The patient, single, aged forty-three, had noticed as long ago as eight or nine years an enlargement in the lower part of the abdomen and on the left side, and this had gradually increased, and latterly had become so painful as to render life almost unbearable. When seen in December, 1884, a rounded smooth movable tumour was found, about the size of a uterus at the seventh month of pregnancy. Operation was performed on February *19th, 1885, and removal* of the tumour was effected by taking up the uterus at the junction of the body with the cervix in segments, and tying each with strong catgut ligatures and cutting through about half an inch above. The edges of the stump were drawn together and dropped into the pelvis. The operation was performed without the spray. The after-progress was detailed. The chief difficulty experienced was the severe gastric disturbance, the patient being unable to take any food by stomach without pain. There was a history of dyspepsia of several years' standing. On March 18th she had an attack of hæmatemesis, vomiting a large quantity of blood, and died the next day. At the post-mortem the external wound was found perfectly healed, and the surface of the stump (cervix uteri) was cicatrised over. The stomach was filled with blood, and a large perforating ulcer was found in the posterior wall adherent to the pancreas, which had evidently prevented extravasation into the abdominal cavity. The specimens were exhibited.

Dr. BANHAM introduced a boy, aged thirteen, suffering from Pseudo-hypertrophic Paralysis, in whom there was marked hypertrophy of the muscles of the calf and buttock, and equally striking atrophy of the muscles of the chest and shoulder, especially the pectoralis major. The weakness of the legs, which was first noticed when he was six years old, had been progressive since that time. The arms had been similarly invaded, and now there was as complete a paralytic condition as is usually met with in the most advanced stages of the disease. No passive exercise having been had recourse to, and the legs remaining constantly in a flexed position, contracture had taken place in the hamstring muscles, and the knee-joints also were considered to have undergone some change. These conditions, whilst they added greatly to his helplessness, had also doubtless favoured degenerative changes. The patellar-tendon reflex was absent, and powerful faradaic currents elicited no response on the part of the calf muscles. There was, however, a feeble contraction of the gastrocnemius on the making of kathodal and anodal currents of ten milliampères. Microscopical examination of a small piece of muscle that had been harpooned from the gastrocnemius revealed the usual excess of interstitial connective tissue.

Dr. DYSON showed the Spleen and Heart from the case of Leucocythæmia which he had exhibited at the Society on March 12th. The patient died on April 17th, after diarrhœa, general anasarca, and great asthenia had supervened; coma suddenly came on half an hour before death. At the post-mortem the abdomen was found to contain a large quantity of greenish-turbid fluid. The spleen weighed 2¼ lb.; the capsule was thickened, and on the surface were three white not raised patches, and on section these were found to be white in colour and triangular in shape, the apex being inwards; they were probably old hæmorrhagic infarcts; the rest of the splenic tissue had the usual features of hypertrophy. The liver weighed 3¾ lb.; a small, whitish leukæmic patch was seen in the left lobe. Lungs healthy. Kidneys large and pale on section, calyx diminished, and capsule adherent; there was a small cyst in the right kidney. The muscular tissue of the heart was pale and thin; the sulci (auriculo-ventricular and interventricular) were occupied by a somewhat firm gelatinous tissue, composed chiefly of lymphoid tissue. The lymphatic glands were healthy, except the post-bronchial, which were pigmented and many calcareous.

Reviews and Notices of Books.

Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Directeur de Rédaction Dr. JACCOUD. Tome XXXVI., 1884 (TR—TYPHO), and Tome XXXVII., 1885. Libraire J. B. Baillière, Rue Hautefeuille, Paris.

THE thirty-sixth volume of this fine dictionary contains the following chief articles:—Trachea and Tracheotomy, by L. Dubar; Transfusion, by Oré; Tremblement, by Picot; Trepan, by Poulet; Trophoneurosis, by Leloir; Tubercle and Tuberculosis, by Hanot; Tumour, by Heurlaux; Tympanites and Typhlitis, by Lutoy; Typhoid Fever, by Homolle and Dreyfous. The thirty-seventh volume contains Typhus (Typhus Exanthematic, Recurrent Fever), and Cerebro-spinal Meningitis, by E. Richard; Uræmia, by Labadie Lagrange; Urethra, by Bouilly, Guiard, and Janin; Urinary Passages, by Bouilly; Urine, by Danlos, Charpentier, and Schwartz.

We naturally turned with interest in the first instance to Dr. Leloir's essay on Trophoneurosis, one of the most recent chapters added to pathology. Dr. Leloir coincides with Charcot that nothing is better established in pathology than the existence of trophic troubles consecutive upon lesions of the nerve centres or of the nerves. The tissues and organs in which these effects have been most distinctly shown are the skin, the muscles, the bones, and the joints; but M. Leloir limits his observations in this article to the trophic lesions of the skin. He commences by pointing out the intimate relation that exists between the nervous system and the skin in regard to their origin, both being developed from the epiderm, and then takes up in succession chronic erythema and superficial dermatitis; vesicular affections, such as certain forms of eczema and herpes; bullæ, including certain localised bullous eruptions and certain forms of pemphigus; pustular affections, including certain ecthymas; ulcerations, including the perforating disease and some little slender forms of trophic ulceration; gangrene; scleroderma; morphœa; facial trophoneurosis; lepra; certain forms of ichthyosis; disturbance of the pigmentary cells of the skin in the direction of excess or diminution, and vitiligo; and finally, lesions of the cutaneous appendages, as the nails, hairs, and sudoriparous and sebaceous glands—a large list, considering that it is but a few years ago since the first cases in which the connexion between the nerves and the skin were adduced by Paget, Weir Mitchell, Brown-Séquard, Charcot, and Bärensprung. The article on Tumours, though of considerable length, is materially reduced from the circumstance that many of the forms are described under their proper names in other volumes. Nearly half of this volume is occupied with the subject of Typhoid Fever, the article upon which has been written by M. Homolle, and gives a thoroughly reliable account of this disease. M. Homolle dwells strongly on the means of disinfection that should be adopted in hospitals, giving his adhesion to the methods recommended by MM. Besnier, Lucas-Championnière, and Baudrimont. Good sections are devoted to antipyretic and antithermic treatment.

The thirty-seventh volume is chiefly occupied with the consideration of five subjects—Typhus, Uræmia, Urethra, Urine, and Uterus. The article on Urine is by M. Danlos, and is a treatise in itself, occupying, with the remarkably complete bibliography of recent works with which it closes, no less than 250 pages. Commencing with Hippocrates, some of whose aphorisms are still pertinent, the author gives a succinct historical review, from the date of that physician downwards, of the advances of our knowledge. The changes which the urine undergoes even in health, and more especially in disease, have always rendered it a favourite study, and, according to Leube, from the time of Magnus of Alexandria to the close of the last century no less than 200 treatises were written upon it; whilst in M. Danlos' bibliography, which includes only the treatises and papers published from the year 1850, upwards of 600 are mentioned. The plan pursued by M. Danlos is that a short account of the physical and chemical properties of urine as a whole is first given, the several constituents are then described separately, and the changes in their quantity or nature effected by disease fully discussed. Throughout the practical side of the subject is considered, the very proper view being taken that the article is written for a Dictionary of Medicine and not for a treatise on physiology. As an example of the mode in which M. Danlos treats contested points, we venture to abstract a part of the section which deals with the changes taken place in the urea after urine has been passed. The formation of ammonium carbonate from urea by the action of acids and alkalies is of course well known, and is due to the urea taking up two equivalents of water.

> "The hydration of urea may proceed in a very different manner, which, however, is full of interest to the physician. Dumas in 1830 gave the chemical equation representing the process. In 1843 Jaquemart, one of his pupils, observed that the deposit which occurs in ammoniacal urine is a very active agent in decomposing healthy urine. This was confirmed by Muller in 1860. Pasteur was the first to recognise, in his celebrated memoir on Spontaneous Generation, the presence of a low organism which he suspected to be the agent of ammoniacal fermentation—a theory the truth of which was demonstrated

by Van Tieghem. The parasite is a torula, named by Koch the micrococcus ureæ. In urine undergoing free fermentation it forms elongated chaplets composed of spherical globules, with a diameter of 0·0015 mm. Light exercises a certain influence on its development, for the side of the vessel turned towards the light is always covered with a more abundant parasitic vegetation than the opposite. The parasite grows and multiplies in highly alkaline media. It develops in a culture fluid containing, in addition to urine, yeast or phosphates, as freely as in urine. Fermentation may proceed in the fluid so long as the quantity of ammonium carbonate does not exceed 13 per cent., according to Van Tieghem. When the process is ended, the chaplets break up, and their elements fall to the bottom of the vessel in the form of exceedingly minute spherules, mixed with ammonium urate and ammoniaco-magnesian phosphate. The ferment of urea exists always and everywhere in the air, though often mixed with other organisms. The truth of this theory has been contested by Musculus, who has shown that a soluble ferment can be extracted from urine capable of converting urea into ammonium carbonate. To obtain it, it is sufficient to precipitate the putrefied urine of a patient affected with vesical catarrh with alcohol, and to collect the precipitate on a filter and dry it. On the addition of water, a substance is dissolved which rapidly destroys urea. Pasteur and Joubert have verified the truth of the statements of Musculus, and shown that the contradiction is only apparent. They have demonstrated that the torula pre-exists in all cases where the soluble ferment occurs, and that this may be regarded as the product of plant life, just as the gastric juice is the product of the cells of the gastric follicles; and it hence follows that the fermentation of the urine is a kind of diastase."

M. Danlos then briefly discusses the statements of Neubauer, Miquel, and Bouchard, and shows how the introduction of unclean instruments may induce decomposition of the urine in the bladder itself. Under the head of each constituent of the urine the quantitative and qualitative tests are given, and the characters of the urine in various diseases are recorded at length. The section on the Uterus, which runs to 340 pages, is divided into several subheadings, of which that dealing with its embryology, vices of conformation, and lesions, has been committed to the charge of M. Charpentier, the anatomy and operations to M. Schwartz, and the pathology to MM. Siredey and Danlos. The serious operation of removal of the uterus seems to have been fairly successful in France; thus Demons reports seven operations with three deaths; two cases remain well after eighteen months, and two have had relapses.

Clinical Lectures on Scrofulous Neck. By T. CLIFFORD ALLBUTT, M.A., M.D., F.R.S., Consulting Physician to the Leeds General Infirmary; and *On the Surgery of Scrofulous Glands.* By T. PRIDGIN TEALE, M.A., M.B., Consulting Surgeon to the Leeds General Infirmary. London: J. and A. Churchill. 1885.

WE are very glad that these two clinical lectures, each the complement of the other, have been published. They deal with a subject which is full of distressful interest to all practitioners in this country; and no men enjoy the confidence of the profession more thoroughly and more worthily than Dr. Clifford Allbutt and Mr. Pridgin Teale. Dr. Allbutt deals with the pathological side of the question, the causes, course, and possible consequences of scrofulous glands. He lays stress upon the origin of the disease in trivial local conditions unperceived at the time, and soon forgotten, and upon the spread of the infection from gland to gland. The disastrous effects of the disease are not limited to the mere local inflammation and destruction of tissue, but include also slow chronic septic infection, and probably also tubercular infection. While clearly indicating the appropriate treatment in the earlier stages of the malady, the chief purpose of the opening lecture is to advocate thorough surgical interference in all cases of suppuration and evident caseation of the glands. Mr. Teale develops this part of the subject, and describes in full the details of the operation he has practised with striking success; and he appends short accounts of several illustrative cases. The lectures are well worthy of the attentive study of all physicians and surgeons; and we believe that the line of practice advocated in them is destined to meet with wide acceptance and be followed by great benefit to a class of sufferers to whom hitherto neither medicine nor surgery has been able to offer much aid. Part of the proof of the first lecture evidently escaped revision, for on page 4 we twice read "diathesis" for "diatheses"; and on page 7 "mucous" for "mucus," and "asceptic" for "aseptic"; on page 8, too, "prolification" must be a misprint for "proliferation."

OUR LIBRARY TABLE.

Endemic Goitre or Thyreocele. By WM. ROBINSON, M.D. and M.S. London: J. and A. Churchill. 1885.—This *brochure* contains the facts and arguments adduced by its author in his thesis for the degree of Doctor of Medicine of the University of Durham, together with subsequently added footnotes, and an appendix giving an account of three cases of cretinism. The thesis was awarded the gold medal of the year 1884. The small work is chiefly a well-arranged and practically exhaustive collection of the facts connected with goitre. One of the most interesting portions of the work is that which treats of the etiology of goitre. St. Lager's observations are quoted, showing that where the sulphide of iron exists in a form readily convertible into sulphate of iron there the endemicity of goitre is most marked. On this point our readers may refer to Dr. Thursfield's paper published in another column. Dr. Robinson gives reasons for believing that there is no diminution of goitre in Stanhope, which lies on the north bank of the river Wear. He states that there is certainly no excess of lime in the drinking water of Stanhope, for he obtained no reaction on the addition of oxalate of ammonium.

On some Common Injuries to Limbs; their Treatment and After-treatment, including Bone-setting (so-called). By EDWARD COTTERELL, M.R.C.S., L.R.C.P., late House-Surgeon, University College Hospital, &c. London: H. K. Lewis. 1885.—This is a readable and useful little book. Mr. Cotterell writes sensibly upon "bone-setting," stating plainly its value and its dangers. Practical hints in the treatment of common injuries of the limbs are given, and special stress is laid upon the importance of the surgeon himself ascertaining that the function of injured limbs is completely restored. Too often splints are removed, and no pains taken to restore perfect mobility of stiffened joints; this is wrong. Mr. Cotterell says so plainly, and gives good rules of treatment for such stiffness. The book will repay perusal, although not actually novel in its teaching.

The Quarterly Journal of Microscopical Science. No. XCVIII. April, 1885. Edited by Professors RAY LANKESTER, THISELTON DYER, E. KLEIN, MOSELEY, and SEDGWICK. London: J. and A. Churchill.—This number contains the following articles:—1. The Urinary Organs of the Amphipoda, by W. Baldwin Spencer; with one plate. 2. The Skin and Nervous System of Priapulus and Halicryptus, by Robert Scharff; with one plate. 3. The Eye and Optic Tract of Insects, by Sidney J. Hickson; with three plates. 4. A Peculiar Sense Organ in Scutigera Coleoptrata, one of the Myriapoda, by F. G. Heathcote; with one plate. 5. The Structure and Development of Loxosoma, by Sidney F. Harmer; with three plates. 6. A New Hypothesis as to the Relationship of the Lunghook of Scorpio to the Gillhook of Limulus, by E. Ray Lankester. The editors state that so many papers of value have accumulated in their hands, that they intend to issue a supplementary number in the course of the present month. It must, however, be specially ordered by subscribers. Amongst other articles they promise one by Oudemans, on the Circulatory and Nephridial Apparatus of the Nemertea; another by W. Bateson, on the Development of Balanoglossus; a third by Baldwin Spencer, on the Early Development of Rana Temporaria; and one by Herbert Carpenter, on the Vascular System of the Urchins.

Lehrbuch der Physiologie. Herausgegeben von Dr. A. GRUENHAGEN. Siebente Auflage, 5te Lieferung. Leipzig: Leopold Voss. 1885.—The present part of this work, which is a new and revised edition of Funke's well-known treatise, completes the first volume and commences the second. It is chiefly occupied with the subjects of the excitability of the nerves, the capacity of the nerves to transmit impressions in opposite directions, the rapidity of nervous conduction, and the nature of nervous stimulation. The work is remarkable for a clear and continuous exposition of the science of physiology, and for the excellent bibliography which is appended to each section.

Dwelling-houses: their Sanitary Construction and Arrangements. By W. H. CORFIELD. Second Edition, with Illustrations, pp. 117. London: Lewis. 1885.—This is one of the best handbooks we have met with on the subject of house sanitation. It states clearly and intelligibly the requisite conditions of a healthy home, indicates the most usual defects, and points out the most appropriate remedies. It is a work deserving the study of all householders who care for their own health and for that of their families.

Shepherd's First Aid to the Injured. Revised and rearranged by R. BRUCE. Pp. 78. London: St. John Ambulance Association. 1885.—This work, by Surgeon-Major Shepherd, who was killed in the unfortunate massacre at Isandhlwana, was one of the first handbooks brought out for the use of the ambulance classes. It still remains, in our opinion, the best manual for the use of non-professional persons to enable them to render aid in cases of accident or sudden illness until professional assistance can be obtained.

Help at Hand: or, What shall we do in Accidents or Illness? By COUNTESS COWPER. Pp. 38. London: Wells, Gardner, Darton, and Co. 1885.—The object of this work is to furnish a cheap guide to "first aid," for the use of Lady Cowper's "own parish." It is to a great extent compiled from Surgeon-Major Shepherd's manual; but the chapter on Anatomy and Physiology has been omitted, probably as being unsuited to the class for whom the book is intended, and one has been added on the treatment of some of the more generally prevalent diseases. We cannot say that we approve of the addition, as we fear it will often have the effect of delaying application for professional advice in cases of serious disease.

Illustrations of Clinical Surgery. By JONATHAN HUTCHINSON, F.R.S. Fasciculus XVII. London: J. and A. Churchill.—The four plates in this fasciculus illustrate Extra-capsular Fractures of the Neck of the Femur, Lupus of Mucous Membranes, Superficial Forms of Rodent Cancer, and Chancres in Unusual Positions. Both the plates and the descriptive letterpress maintain a high order of merit; and those who take in this serial work possess a very valuable book on clinical surgery.

The Tricycle in relation to Health and Recreation. By B. W. RICHARDSON, M.D. London: W. Isbister. 1885.—The papers collected in this volume, except a few additional notes, were published in *Good Words* a year or two ago. The main questions which the author endeavours to solve are: (1) whether the tricycle can be safely used by all classes of the community, or whether it is only fitted for a select few; (2) whether the working of the tricycle is healthful as an exercise; (3) whether there are any special dangers from its employment which, apart from mere accidents from falls and collisions, militate against its general use; and (4) whether there are any practical rules which can be offered for the guidance of those of different sex and different age who are anxious to become riders. These points are all fully discussed by Dr. Richardson, and to all intending to commence the use of the tricycle we can recommend a perusal of this little book.

New Inventions.

NEW MICROSCOPES.

M. THEILER & SONS, of 86, Canonbury-road, London, N., have brought under our notice specimens of their "Demonstration Microscope" and the "Universal (Achromatic) Pocket Microscope." Both are of novel design, and remarkable for the simplicity of their construction, the excellence of their manufacture, and the facility with which they may be manipulated. Intended for the observation of translucent or semi-transparent objects only, mirrors and condensers are in the use of these instruments dispensed with. The method of adjusting and fixing the focus is simple and ingenious. We anticipate that a wider knowledge of the convenient arrangement and the low price of these microscopes is all that is necessary to create for them a large demand.

SANITARY SEAMLESS STEEL SAUCEPANS.

THE increasing interest taken in the art of cookery, and the wider recognition of its importance from a public health point of view, have naturally stimulated invention in the direction of devising utensils more in harmony with the advancing intelligence in respect of the elements included in the question of the proper preparation of food. Messrs. Perkins and Son, of Bermondsey-street, have contributed to the perfecting of the process by introducing seamless steel saucepans and stewpans, for which they were awarded a silver medal at the recent Health Exhibition, and which were used at the School of Cookery in connexion therewith. These accessories to the *cuisine* are certainly quite worthy of the approval bestowed on them, and are a great improvement upon the cast-iron and copper culinary vessels hitherto employed. The ease with which cleanliness may be ensured in their use, to say nothing of their superior durability and sightliness as compared with the ordinary ware, ought to secure for these utensils extensive patronage.

THE PARLIAMENTARY REPRESENTATION OF THE UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.

To the Editor of THE LANCET.

SIR,—The Conservative Committee have, with the haste characteristic of sharp electioneering tactics, sent round a circular in which, putting forward as a plea the abrupt retirement of Sir Lyon Playfair, they quietly assume that Mr. Macdonald is to be allowed without opposition to take his seat as representing these universities. With a constituency consisting of so large a predominance of scientific men, it is to be hoped that some man of scientific eminence may be found to contest the election with the legal profession. I trust that my fellow-graduates will not hastily be induced to throw up their interest in Liberal politics, led astray by the plausible statements of the Conservative Committee, who would fain persuade us that no alternative can be found to the return of Mr. Macdonald.

I am, Sir, yours obediently,
M.D. ST. AND.

June 8th, 1885.

AT a meeting of the Metropolitan Asylums Board on the 6th inst., it was stated that the returns of small-pox for the fortnight ending the 5th inst. showed a decrease of 97 in the total number under treatment in the hospitals of the managers. The number under treatment on the 5th inst. was 1247.

THE LANCET.

LONDON: SATURDAY, JUNE 13, 1885.

WE are again confronted with the great question of Hospital Sunday. The institution is no longer a local one, confined merely to Birmingham or London, but it exists in almost every town that boasts of a hospital, and promises to be as general and as successful in the United States as it is here. In every aspect of it Hospital Sunday is a thing to be encouraged and supported. The most creedless man must believe in the existence of an untold amount of physical suffering in a community like that of the metropolis, for which the pent-up homes of outcast London afford no accommodation. It is not for us to open too widely the windows of London hospitals and to expose the mass of disease with which the medical profession is contending, for the most part without fee or reward. And not the medical profession alone, but the dozen or score of gentlemen who, almost more benevolently, undertake the administration of hospitals in days when criticism is sometimes more active than charity. It has always been our regret that the ministers of religion in London do not see the hospitals on the Saturday preceding the Sunday on which they are to preach those sermons which in the last twelve years have produced the large sum of £358,256 11*s*. 1*d*. for London medical charities. There is something exceedingly eloquent in a well-ordered hospital: the sweetness of the air, the tenderness of the medical and nursing service, the adaptation of apparatus and of diet, and the obvious comfort of the majority of the cases, would supply data that should strengthen the argument of the best preacher, and perhaps double the contributions of the congregation. While the accommodation for the living and the strong in London is so unsatisfactory, it is pleasant to know that in a London hospital there is accommodation and skill for the sick which the richest might envy. The poor patient with fever, with consumption, with incipient cancer, with an imperilled eye, with an exhausting suppuration, with joint disease, or with the misery of tumour or of calculus, cannot wait. Every day makes his case worse and his prospect darker. And yet every day such cases are kept out of London hospitals from want of funds, or from want of room. In two even of the great endowed hospitals whole wards that were meant for the poor have had to be appropriated to those who can pay. We have entered our protest against such an alienation of London hospitals; but it still exists. It has a certain fascination for embarrassed treasurers, and will certainly be extended if care is not taken. The treasurers cannot reasonably be charged with the whole blame. They say that they would willingly keep the wards for the poor if the funds were forthcoming. But they are not. Rents of hospital properties have to be reduced. Subscriptions have fallen off. And to ask the treasurers to keep wards open without giving them money is like requiring the Israelites to make bricks without giving them straw. There is a certain amount of truth in these statements. What is the remedy? The remedy is in more generous subscriptions, and a larger Hospital Sunday collection. There is no other remedy. It is astonishing to notice the large number of persons who contribute nothing to charities. Mr. BURDETT has found that in a town with twenty-five charities and 350,000 inhabitants, only 6000 persons of the whole number contributed. He was very careful to count all contributions, great and small, and yet he had to conclude that only one in fifty-eight contributed to support charities; and he considers that this town represents most other communities. The Hospital Sunday Fund has put it within the easy power of all to make their contribution to this cause. It is not meant to supersede personal subscription and interest on the part of the wealthier classes. But it is meant to appeal to all to help to make a comfortable bed for the sick, the wounded, the maimed, and the blind, that they may be healed; or if this may not be, that their misery may be abated. The average annual amount of the metropolitan collection for the last twelve years has been £29,854. This is a great sum in itself; but when considered in connexion with the suffering which it is meant to meet, or with the means of those to whom appeal is to be made on Sunday next, it must be pronounced to be inadequate. No excuse will avail for this supreme neglect. "I was sick, and ye did not minister to me." It is of no avail to say that treasurers sometimes do not spend the money wisely, or that now and again a person who can pay occupies the bed that misery should claim for its own. This is only to say that the administration of hospitals is in human hands. Let all abuse be weeded out. The Council of the Hospital Sunday Fund has done great good in this direction, and has on this ground a strong claim to the confidence of those who wish wisely to help medical charities, whether in the way of a contribution on Hospital Sunday, or of a legacy that will permanently help the sick poor of this huge and complex community. We give in another column a list of hospitals which are at the present time suffering from the crippling effects of lack of funds.

◆

How are the prospects of medical legislation likely to be affected by the political crisis which has occurred? At the moment of going to press we do not certainly know whether there will be an immediate transfer of authority to the opposite party, or if the still existing Government will retain office until the natural expiration of a moribund Parliament. Whatever the eventuality, it seems only too certain that the prospects of legislation for the reorganisation of the profession and the advantage of the community in matters medical must be irretrievably damaged so far as the present session is concerned. Looking back on the last five years, it is only an act of justice to record the fact that seldom, if ever, within an equal period has the medical profession received so many honours from the hands of a Prime Minister as Mr. GLADSTONE has distributed, and we are glad to acknowledge that for this measure of favour we are directly indebted to the enlightened and generous appreciation of services and usefulness shown by the gifted statesman who is now, it is to be feared, finally resigning the control of public affairs. It is not for us to speak of general politics. Science has no knowledge of party, and can only concern itself with the public good; but it will not be thought out of place by any of our readers that we should express the strong persuasion that the respect, and if we may say so, the esteem of the medical profession will follow Mr. GLADSTONE into the retirement he seeks. If some of the subordinate members of his adminstration have been less appreciative, and shown less wisdom, that is a disappointment which, however keenly felt, cannot detract from the estimation in which the medical men of of this country—as a profession—must needs hold the outgoing political chief.

There are some commotions out of which good may come to all who are affected. This cannot be our case as medical reformers. For the present certainly, and the near future we fear, medical reform will have to wait. There is no reasonable prospect that the measures which it was hoped the session might see matured will find a place in the programme of a reconstructed Cabinet or of the incoming Government. We wish we could feel hopeful as to the chance of medical reform engaging the attention of the new Parliament. There is only too much reason to anticipate that, however advantageous the extension of the franchise and the consequent reconstruction of the Lower House may prove, for some at least, the spirit of vestryism will dominate the counsels of the nation, and domestic legislation will take the form of *political* sweeping and garnishing, rather than of a broad and intelligent ministering of justice to the great public needs.

If the Conservatives should hold office, we are bound to confess that—all party views and sympathies apart—it would be absurd to expect that medical men and their opinions will count *for* much. The healing art has little interest for the *aristocratic* party in politics. To be a "doctor" is to be beneath regard, unworthy of honour; and to speak of the interests of health, except in a meaningless phrase, is to introduce a topic too vulgar for delicate ears. Medicine, whether as a science or as a profession, has little to hope from the party which never once in six years conferred an honour on any member of the medical body; and, though it talked much, did nothing—or, if possible, less than nothing—for the advancement of science and the encouragement of those whose lives are spent in a ceaseless struggle to reduce to practice the fruitless aphorism, *Sanitas sanitatum, omnia sanitas.*

◆

THE extension of the franchise in its political bearings is a subject beyond our care. Both parties in the State have sanctioned it and actually co-operated in arranging it, so we may presume there is some deep justice, some deep necessity in the measure. Our concern is with the moral and social consequences of it. Millions of our humble fellow countrymen are to be endowed with grave political functions. It is not denied that many of these millions are ignorant and unintelligent, but it is supposed that by some divine instinct in the people they will be led to great and true conclusions. We hope it may be so. We are not disposed to think quite so meanly of the people as even MILTON did.

> "And what the people but a herd confused,
> A miscellaneous rabble, who extol
> Things vulgar, and, well weigh'd, scarce worth the praise?
> They praise and they admire they know not what
> And know not whom, but as one leads the other."

What we may fairly ask for in the new voters is an increase in the sense of independence, of that creditable pride which makes men almost starve rather than ask alms or parish relief. The question of disfranchisement for medical relief, which, like so many other questions, serves for Parliamentary strife and debate, should settle itself in the conscience of honest men, who should disdain to ask a voice in the settlement of national affairs till they have shown themselves capable of managing their own. How can a man receiving parish relief have either the conscience or the intelligence to vote? We demur to the doctrine that to be on the parish for medicine is different from being on the parish for a loaf of bread. We can recognise no such distinction, and we think it high time that it was exploded. Medicine is a rarer and a lesser want than food, and there is by so much the more discredit in an improvidence which does not recognise its humble claims. Medical men have been too long the scapegoats of the improvidence of the poor on the one hand, and of the scanty charity of the rich on the other. And the Franchise Bill will have a much-needed vindication if it intensifies the sense of personal responsibility in the humblest man, and makes him feel it a mean thing to go on the parish for a bottle of medicine or even for a serious illness. The humanity of the medical profession needs no vindication. It has had ample recognition from all judges and all classes. It makes the most generous provision for the poorest, and it is now for the poorest to break with all pauperising associations and to maintain their own independence and political power by entering provident clubs, in which a medical officer is fairly well paid, and in which the patient, when sick, can find not only an efficient medical man, but temporary allowances of money. No greater mistake could be made than to introduce the Irish dispensary system into England, it being greatly abused even in Ireland; and there is a great risk of doing this if we make fine distinctions between medical and other forms of relief. If the working classes are to derive benefit from the franchise, it will be by raising in them the sense of their importance and of the meanness of dependence on rates, either for medicine or anything else. Very little self-sacrifice will suffice to prevent the disfranchisement of voters on the score of medical relief, and the man who will not make it is presumably—there will no doubt be honourable exceptions—unworthy of the franchise.

◆

HEADACHE, although so common an affection, possesses a peculiar interest on account of the tantalising obscurity in which its cause is often shadowed. Depending upon one or two main physiological principles connected with the passage of nervous impulses and the calibre of cerebral bloodvessels, it yet arises in response to so many different stimuli, that, practically, the branches of its original stem of structure, its distributive variations, are perplexingly numerous. Among the forms but recently described and named, though probably as old as Art, is the "academy headache." Critics and doctors have vied with one another in trying to translate this term according to the rules of medical logic, but have not, so far, been able to agree as to its meaning. In venturing to put forward our own opinion on the subject, we think it best to notice the different circumstances which tend to produce in the frequenter of galleries that general sense of fatigue which is often the precursor of pain, and then to note the special stimulus which brings out of this chaos the formed and local ache. It should be noted that all do not suffer from this form of headache; while of those who do, some are less and some more affected. Fatigue may be the limit of annoyance with a certain class. They are heavy-limbed and heavy-headed, languid, but no more. The forces at work upon them are the warmth of the crowded room, the summer sunshine pouring through the skylights, the listless rotation or circulation, rather than walking, through the rooms, and the weariness of much-divided attention. Being robust and used to go about upon their feet, they soon lose the feeling of languor after its causes cease to act; and if their eyesight be equally healthy, they suffer no strain in these organs. There are other persons, of weaker organisation or more sedentary habits, in whom pain quickly follows fatigue, and it is felt, for certain reasons, chiefly in the head. Among these reasons we must note the fact that in the standing position the blood, driven by a languid heart, reaches the head with greater difficulty than when recumbent. Anæmia is one cause of headache. Anæmia, too, is associated with changes of arterial calibre which constitute the usual cause of megrim. Under these conditions, also, the giddy malaise of a loitering gait is painfully perceptible. Concentrated attention increases the uneasy sensation. The frequently constrained position of the head has its influence. It would be strange, moreover, if ocular movements had no share in the production of this complex indisposition. Let anyone converge his eyeballs to an acute angle, as in squinting, or let him direct a sidelong glance of extreme obliquity, and a single effort will convince him of the pain of such muscular effort. No doubt this is the pain of muscular tension, acute and so far abnormal; but it is also possible to induce a similar pain from the strain of too frequent muscular action within the normal limits of accommodation to distance or other movements of the eye. Ocular pains of this kind are felt as an aching about the middle and back of the head. The scrutiny of paintings or engravings, from the many points of interest which have to be noted, requires a considerably greater exercise of the muscles of the eyeball than is called for in ordinary life. In this fact, established, as we have already stated, on a basis of fatigue and general muscular and nervous strain, we have probably the usual exciting cause of the form of headache we have been discussing.

Annotations.

"Ne quid nimis."

THE COLLEGE ELECTION.

FOR the three vacancies in the Council of the Royal College of Surgeons of England there will be seven candidates—namely, Mr. Savory, who seeks re-election, and, in their order as Fellows, Messrs. Gant, F. Mason, Rouse, Cowell, Macnamara, and O. Pemberton. It will be remembered that the other retiring members, Messrs. Erichsen and Holmes, do not desire re-election. This is a regrettable circumstance, as both these gentlemen are avowed supporters of a policy of reform. Their withdrawal from the Council at this time may therefore seriously cripple the action of the party favourable to progress. At all events, it suggests a more careful selection of candidates and a closer scrutiny of their views. It would save some misunderstanding and possible recrimination if all candidates were to set forth briefly and succinctly their political doctrines. For the last two or three years several candidates have owed their election to a general belief that they would support certain projected attempts to place the Council *en rapport* with the Fellows and Members. No sooner were they elected than they gave their votes in favour of maintaining the *status quo antea*. While it would be unjust to impugn the probity of these members of the Council, it is impossible to acquit them of culpable political incapacity, indifference, or ignorance. Such a contingency should not be possible. If a candidate is not prepared to make a declaration of his political faith and belief, he ought at least to have the courage not tacitly to accept imputations which, though favourable to his election, are contrary to his convictions.

MEDICAL DEGREES AT OXFORD.

ON Tuesday last, the 9th inst., the preambles of two statutes of great importance to candidates for the medical degrees of this University were approved. By the first, a Faculty of Medicine distinct from that of natural science was constituted, and the professors of anatomy, botany, chemistry, experimental philosophy, medicine, natural philosophy, and physiology were assigned *ex officio* to the Board of the Faculty. By the second, the examinations for the degrees will be materially changed, and the alterations are very freely criticised. Exception is especially taken to the proposition that any candidate may be exempted from the whole or any part of the examinations in medicine, surgery, or midwifery, if he has passed a qualifying examination in these subjects approved by the Board. It is evidently intended by this clause that candidates for the final M.B. examination should have previously passed the Conjoint Board of the Colleges of Physicians and Surgeons, and to this the Oxford medical graduates are unanimously opposed. They urge very forcibly that Oxford has nothing to do with the corporate examinations, which are only put forward as a necessary minimum of medical knowledge, and that it will make a false step if it allows the principle that the University can accept an examination carried on independently of itself as the equivalent of its own. The subjects proposed for the three examinations for the M.B. degree are—for the first, elementary anatomy and physiology, organic chemistry, materia medica and pharmacy; for the second, human anatomy and physiology; for the third, medicine, surgery, midwifery, pathology, pharmacology, and climatology.

THE ETIOLOGY OF ERYSIPELAS.

THE now fairly well determined fact that erysipelas is a disease due to the invasion of micrococci has not hitherto led to a sufficient explanation of the varieties of the disease, and particularly of the points of difference and of resemblance between traumatic and idiopathic (so-called) erysipelas. In an interesting study of the subject in Virchow's *Archiv* (Bd. 100, Hft. 2), Dr. Rheimer, pathological assistant at Zurich, after reviewing the evidence as yet adduced concerning the nature of erysipelas, details the results of his examination of two cases of typhoid fever in which this complication occurred. The cases arose in a very severe epidemic which took place in Zurich in the spring of 1884, and he contrasts the microscopical characters of the affected skin, and other tissues obtained from them, with those observed in traumatic erysipelas. In the latter he describes not only masses of minute cocci in the lymphatic spaces and vessels, but also very definite chains of larger cocci and diplococci, apparently the same as those originally described by Recklinghausen, and since by Lukomsky, Koch, Ziegler, and many others. In the typhoid erysipelas these last-named micro-organisms were conspicuous by their absence; for although the minuter forms were present in much the same situations and character as in traumatic cases, there were, instead of large micrococci, a number of mostly straight rod-shaped organisms scattered throughout the tissue. These organisms stained badly with reagents, and were apparently identical with the bacilli which Klebs, Eberth, and Gaffky have found more or less constantly in typhoid fever. Although the fact of the existence of a "*bacillus typhosus*" is still *sub judice*, and has indeed been contested by many, it receives a certain amount of confirmation from this discovery. The latter has, however, a bearing upon the etiology of erysipelas, as indicating that the cutaneous lesion—i.e., the dermatitis—may indeed be excited by more than one kind of poison, or, perhaps, to speak more correctly, by more than one kind of microparasite. It may be that there is a specific erysipelas organism for the traumatic affection; but it is possible that the spontaneous cases, and especially those which arise as complications of other infective diseases, own a different etiology. The question is a suggestive one, and offers a fertile field for further research.

FAITH-HEALING A FACT.

THERE can be no question that faith-healing is a fact. The brain is not simply the organ of the mind, it is also the chief centre, or series of centres, of the nervous system by which the whole body is energised, and its component parts with their several functions are governed and regulated. There is no miracle in healing by faith; whereas it would be a miracle if the organism, being constituted as it is, and the laws of life such as they are, faith-healing did not under favourable conditions occur. The fallacy of those who proclaim faith-healing as a religious function lies in the fact that they misunderstand and misinterpret their own formula. It is the *faith* that heals, not the hypothecated source, or object, of faith outside the subject of faith. The whole process is self-contained. Nothing is done for the believer; his act of believing is the motor force of his cure. We all remember the old trick of making a man ill by persistently telling him he is ill until he believes it. The contrary of this is making a man well by inducing him to believe himself to be so. The number of the "miracles" performed will be the precise number of the persons who are capable of being thrown into a state of mind and body in which "faith" dominates the organic state. Pathologists will limit the area of this process to the province of functional disease; but we are not sure that they are justified by scientific facts in making this limitation. It must not be forgotten that function goes before organism in development, and that there are large classes of cases in which the disabilities of a diseased organ for a fair performance of its functions are mainly due to want of power or irregularity in action. And it is a fact in pathology, that if the function of an organ be maintained or restored much of the destructive metamorphosis due to proliferation of connective tissue, fatty deposit, or even certain forms of atrophic change in which the nuclei of cell-life are rather denuded than destroyed, may be arrested and to some extent repaired. The *vis medicatrix naturæ* is a very potent factor in the amelioration of disease, if only it be allowed fair play. An exercise of "faith" as a rule suspends the operation of adverse influences, and appeals strongly through the consciousness to the inner and underlying faculty of vital force. There are many intractable cases in every practice which might be "cured by faith." It is well that these poor persons should be benefited by some means, it matters little what; and if they can be "healed by faith" we ought to be very glad, and thankful too, for the mistaken zeal of those who, being weak-minded themselves, make dupes of other weak-minded folk to their advantage. This is a blind leading of the blind in which they do not fall into the ditch, but, by a happy combination of circumstances, actually escape danger and gain something to boot.

INCONCLUSIVE EVIDENCE OF THE CAUSE OF DEATH.

AN inquest was held at Horninglow, on June the 3rd, before Mr. A. Flint, coroner for the district, touching the death of Mrs. Millar, aged twenty-seven, wife of the vicar of the parish. It appears that the deceased, who was in her usual health on Sunday evening, May 31st, retired to her bedroom at half past ten o'clock, seeming then a little unwell, and at eleven—half an hour afterwards—she was discovered dead on her bed. There was nothing in the surrounding circumstances to explain or suggest the cause of death beyond lividity of the face and blueness of the lips noticed by the husband of the deceased. Dr. W. G. Lowe, who saw the body some two hours later, deposed that there was "a little livid discolouration of the nose, and her lips looked a little blue, but not markedly so; the rest of the face was pale." At the autopsy no organic disease was discovered. A small piece of orange pulp was found in the mouth, but it had clearly not caused death by impaction in the glottis. We cannot agree with Dr. Lowe when he says: "There would have been more indications" if poison had been taken, for it is well known that certain narcotics and convulsants leave no characteristic sign of their action. We have no reason to believe that death arose from other than natural causes, as found by the jury; at the same time we hold that the evidence was sufficiently equivocal to warrant further inquiry. No mention is made in the report of the inquest whether the urine was examined or not. Was there albuminuric eclampsia? Was there diabetic coma? Was the deceased subject to epilepsy in its minor manifestations? Was there a neurotic family history? These are questions that suggest themselves for investigation. Diabetic coma rarely ends so quickly as to be a probable explanation of this case, but we want further experience of the variations to which this peculiar and interesting state is liable. Mrs. Millar may have died from natural causes—apparently she did; but notwithstanding, it is matter of regret that the proximate cause of death was not brought within narrower limits.

A POISONOUS CARPET.

ANOTHER and aggravated example of poisoning, apparently by arsenic, is said to have occurred in New York. A green carpet, which was cut and sewn by the lady who purchased it, acted in this case as the *medium of conveyance*. The symptoms present are not detailed. They were, however, severe, and unexplained by any circumstance until traced to the carpet referred to, and this article was found on analysis to be loaded with pigment of the *most dangerous* kind. Such cases are, unfortunately, too old in memory, and too unmistakable, to afford in themselves much material for comment. One important fact is recorded in the instance before us, and is well worthy of general imitation. The local sanitary authorities have taken the matter in hand, with the intention of prosecuting the manufacturer of the carpet, and will thus do what they can to prevent the occurrence of such culpable mishaps in future. This is the most effective method of dealing with such cases of domestic poisoning. Unless the source of the evil is stopped, there is obviously little hope of a permanent cure. The mere treatment of its effects will not suffice. The purchaser of dyed material on his part cannot be expected to distinguish at sight a noxious arsenical or other dye from a harmless one of exactly similar hue. He usually and almost inevitably derives his proof of quality from painful experience. The subject therefore is clearly one which calls for penal regulation at an earlier stage, and the example set by the Sanitary Board of New York will not, we hope, be lost upon our own Legislature and Executive body.

AN INFECTIOUS DISEASE HOSPITAL FOR NOTTINGHAM.

The Corporation of Nottingham have just decided to purchase 126 acres of land situated, not, as stated last week, on the site of the dwellings to be demolished, but outside the town and some two miles distant from the market-place, for the purpose of erecting thereon a new hospital for infectious disease. They have certainly acted wisely in the step they have taken; the situation of the existing hospital is open to much criticism, and, as we have before pointed out, has had in its immediate neighbourhood, when used for the reception of small-pox patients, a suspicious number of cases of this disease. By going to the intended site they will escape this risk, and will doubtless be able to save themselves in the future the expenses of litigation, which have made small-pox hospitals so costly to London ratepayers. But to avoid litigation is not, however, the whole object to be considered. Nottingham will judge the matter from a higher point of view than is possible for London under existing government. In Nottingham the hospital is to be used for the prevention of infectious disease; in London the primary object of similar institutions is for the treatment of persons suffering from this class of malady. The difference between the two purposes is worthy of observation.

THE TREATMENT OF CHOLERA.

The current number of the *Practitioner* contains the concluding paper of the interesting series that have been published in that journal by Drs. Lauder Brunton and Pye-Smith, in the course of which they have discussed the present knowledge of the pathology of cholera. Speaking of the treatment of the disease, they divide remedies into five classes: of these, three contain remedies which act on the intestine. They are—1. Those which are likely to have an antiseptic action on the intestine by destroying any organisms there present, such as carbolic acid and its allies, sulphurous acid, nitro-muriatic acid, hyposulphites, permanganates, chlorine, chloralum, turpentine, salts of copper, boracic acid, calomel, and corrosive sublimate. The cholagogue action of calomel is thought to be of service by inducing indirectly the antiseptic action of bile. 2. Those remedies which will tend to remove the cholera poison, whether it consists of living organisms or of some chemical substance, exemplified by the treatment by castor oil and other purgatives. 3. Those remedies which will counteract the effect of the poison upon the intestinal canal, as opium, morphia, ice water, belladonna, cannabis indica, chloroform, chloral, carminatives, and astringents. 4. Remedies which will tend to eliminate the poison from the system, as copious draughts of water (as diuretic) and purgatives. 5. Those remedies which will counteract the effects of the poison—viz., intravenous injection of saline fluids and other substances, and various measures to restore the circulation by acting upon the skin. In dealing with the premonitory diarrhœa, Cantani's method of injections, by means of the long intestinal tube, of laudanum and tannic acid is described. The authors consider that Ferrán's results of inoculation are more favourable than could have been expected, and point out the following as "directions in which further researches after a remedy for cholera are most likely to prove successful":—"1. The discovery of an antiseptic which will destroy pathogenic organisms in the intestine and prevent the formation of the cholera poison, while they are not themselves poisonous. Corrosive sublimate is a sufficiently powerful antiseptic, but it may itself prove poisonous to the patient as well as to the pathogenic organisms. It is possible that amongst the members of the aromatic group of bodies substance may be found having the desired properties. 2. The discovery of some substance which will antagonise the action of the cholera poison after its absorption. As a preliminary step in this direction further experiments are needed in the nature and action of alkaloidal substances obtained from cholera dejecta, as well as from artificial cultivations in various media and under various conditions, electrical and otherwise. 3. Observations on the effect of stimulation of the mesenteric plexus by currents passed through the uninjured abdomen in poisoned animals and in patients suffering from the disease."

THE DARWIN MEMORIAL STATUE.

On Wednesday last the Prince of Wales accepted, on behalf of the Trustees of the British Museum and for the nation, a statue of Darwin. There was a large gathering of scientific men, and the statue, which is the work of Mr. Boehm, has been placed in the Great Hall of the New Natural History Museum at South Kensington. Mr. Huxley, who was chairman of the committee and is the President of the Royal Society, made a characteristic speech, in which he pointed out that the publication of the "Origin of Species" practically effected a revolution in science, whilst its effects were even now being felt in many other departments of human knowledge. Vehemently opposed in the first instance, the foundations of that work were laid so deeply, and its conclusions were so well supported by facts, and afforded such satisfactory solutions of problems long regarded as insoluble, that, even within the author's lifetime, he had the satisfaction of feeling that his views were accepted by naturalists in every country, and the majority were engaged in applying them in their every-day work, rather than in attempting to dispute their value and accuracy. The subscriptions for the statue have been sent in from almost every civilised country, and the interesting statement was made that from Sweden alone 2296 subscriptions were received, the donors differing in station from the bishop to the seamstress, and the sums from £5 to 2*d*. The statue has been erected from a small part only of these subscriptions; the major part is to be applied to what the modest philosopher would have most desired—the promotion of biological research.

POISONING BY PENNY ICES.

In the year 1878[1] we drew the attention of the profession to the manufacture of penny ices, showing their composition and the quality of their ingredients. In the following year, 1879,[2] a Lancet Sanitary Commission reported on the condition of the Italian quarter, and described the mode of life and surroundings of the London penny ice man when at home. We fear that as great a necessity for supervision by the local sanitary authorities exists now as when the inquiries were made, and that chemical examination of samples of the ices should be made from time to time as then recommended. During Sunday, June 7th, and Monday, June 8th, more than twenty people suffered from symptoms of irritant poisoning, which came on about two hours after partaking of penny ices bought from one of the Italian street barrows. Thirteen of these were treated by the house physician, Mr. R. M. Williams, at St. Thomas's Hospital, the symptoms being similar, but varying in severity. The most severe case was that of a woman aged forty-two, who was admitted. She arrived about four hours after eating one of the ices, suffering from severe colicky pains, diarrhœa, some vomiting, dryness of the fauces and tongue, and collapse. An emetic was given, which produced free vomiting; later she was given some carminatives, with ammonia, and was able to return home on the following day. Some of the cases treated at their own homes were quite as severe as this. It was difficult to say what was the cause of these symptoms. The day after these people were poisoned the contents of the ice-bowl were examined, but with negative results. Examination of the vomited matter, however, has proved the presence of sufficient carbolic acid to explain the symptoms, and it is probable that this found its way into the ices from carelessness on the part of the maker; carbolic acid being used in the earlier stages of manufacture of a preservative material which is employed by the men to prevent decomposition of the ingredients used in making the various ices. Either the chemical processes had not been carried out to their full extent, and the solution used contained much free acid, or the acid itself had been employed by mistake.

LOZANO ON THE MORTALITY OF MADRID.

DR. G. G. LOZANO endeavours, in a series of essays just reproduced in pamphlet form, to account for the high rate of mortality existing at Madrid. He complains that medical students have but little instruction given them in the diseases of children, amongst whom the mortality is especially high. In his own case he says that he had but a single lesson, from an eminent professor it is true, in the diseases of childhood, and as, when he began practice, his first patients were children, he found himself in an unpleasant situation. There is plenty of clinical material for such instruction in Madrid if it were made proper use of. He complains also of the number of *curanderos*, or quacks, and tells a story about one who "put the bone in" in a case of abscess, which could probably be matched by many an English surgeon who happens to practise in the vicinity of a bone-setter. Small-pox claims a considerable number of victims. Señor Lozano, however, does not discuss the efficiency of the arrangements for vaccination, though he enters at some length on the subject of the importance of a new hospital for contagious diseases, with especial reference to variola. He passes over in a few words the subject of general hygiene, and we look in vain for any proposal for a satisfactory system of drainage, which must be sadly needed in Madrid. A good deal is made of the want of ventilation, and of the injurious crowding in theatres and cafés, and some mention is made of the vices of the inhabitants. The writer is very dissatisfied with the death-rates as published; that of Madrid is, in his opinion, too high, and that of London too low, his respect for the figures in the "Annual Summary" of Messrs. Eyre and Spottiswoode being very small.

EXCITABILITY OF THE CEREBRAL CORTEX.

AT recent meetings of the Académie des Sciences M. Vulpian has continued his demonstrations on some of the functions of the cerebral cortex. He points out that in the dog the effect of an equal stimulus is greater at the facial centre of the cortex than it is at the brachial or crural centres. Pflüger's theory, that a nervous impulse gathers force as it passes along a nerve (avalanche theory), is rejected. If the avalanche theory be true, then stimulation of the crural centre of the cortex ought to give rise to a more energetic contraction than stimulation of the facial centre. The opposite is notoriously the case. Vulpian believes that electrical excitations must be stronger in order to put into action the posterior limb than those used to provoke a facial movement, not because there is any real difference in the excitability of the grey matter of the two regions, but simply because of the distances which separate the centres from the muscles. In the same way, if the dog be anæsthetised by successive doses of chloral hydrate, a time arrives at which a certain stimulation of the cerebral cortex fails to excite a movement in the limbs, whilst the same stimulus may call forth a movement of the face. The reason, according to Vulpian, of this difference is simply that the impulse originated by the electric stimulation has a less distance to pass before it reaches the facial nucleus than it has to reach the nuclei governing the movements of the limbs. Vulpian argues in favour of a uniform excitability of the grey matter of the so-called motor centres.

THE LATE PROFESSOR COHNHEIM.

THE numerous contributions to pathological science which Professor Cohnheim made during the twenty years of his active scientific career have been collected into a volume ("Gesammelte Abhandlungen von Julius Cohnheim." Berlin: A. Hirschwald), under the editorship of Dr. E. Wagner. The papers and monographs, thirty-eight in number, are mostly reprinted from Virchow's *Archiv*, to which Cohnheim was a constant contributor. They are arranged in chronological order, opening with his essay on Inflammation of Serous Membranes (1861), and closing with his Studies on Renal Circulation, made in conjunction with Dr. Charles Roy (1883). Between these two how many familiar subjects are to be found in essays that have attained a world-wide renown! Here, for example, is the famous paper on Inflammation and Suppuration (1867), and the well-nigh as celebrated Researches on the Embolic Process (1872); followed by those studies upon circulatory disorders, œdema, dropsy, &c., which seem naturally to flow from the new ideas. Here, too, is his suggestive paper on Tumour Metastasis, and his celebrated address on Tuberculosis, which may be said to have anticipated the subsequent discoveries of Koch. Besides these there are many contributions to pathological anatomy. The volume, taken together with the well-known "Vorlesungen über Allgemeine Pathologie," forms a lasting memorial of the ardent student and teacher, who, in spite of continued ill health, contrived to contribute so largely to knowledge, and to inspire so many with a like zeal for research. The value of the book is enhanced by a memoir of the author from the pen of Professor W. Kühne, who knew him well, and who testifies to the severe loss sustained by his early death. A portrait of Cohnheim is prefixed to the volume. Many who knew him only by his work will doubtless be glad to possess a volume which those who did know him personally will cherish as embodying the history of his career, for his life compels admiration not only for the genius he possessed, but for his nobility of character and the steadfastness with which he pursued his duties under obstacles that would have crushed a man of less abundant energy.

TREATMENT OF RICKETS.

DR. SEMZCHENKO writes to a St. Petersburg journal that he was induced by the successful results obtained by Kassovitz in the treatment of rickets by phosphorus to make trial of it, notwithstanding the adverse statements of Henoch and Schwechten. He gave it to fifteen children from eleven weeks to twenty-two months old, all other medicine being intermitted during the trial of the phosphorus, which was prescribed in an emulsion with sugar and gum. It was only stopped when severe vomiting occurred. He came to the conclusion that it was an utterly useless mode of treating these cases, and reverted to his usual method of managing rickety children, which consists of giving salt baths daily, the head being washed with warm water and the whole body with brandy-and-water. Internally tannate of quinine (one to two grains) is administered with one-eighth of a grain of extract of secale in from two to four powders daily. They are fed with bouillon, boiled milk with from one to two tablespoonfuls of lime-water and from a quarter to half a teaspoonful of cognac to the tumbler. Children at the breast are given a teaspoonful of lime-water and glycerine from two to four times a day. When they have large abdomens, enemata (one to two tumblerfuls), containing from fifteen to forty grains of salicylate of soda, from ten to thirty grains of borax, or from two to three tablespoonfuls of a 1 per cent. solution of carbolic acid, are given. In from one to two months the little patients invariably show a marked improvement under this method of treatment.

THE LATE MEDICAL OFFICER OF HEALTH FOR LEICESTER.

WE hear with much regret that Dr. William Johnston has resigned the appointment of Medical Officer of Health to the Borough of Leicester, which he has held for seven years. Dr. Johnston's excellent work during this period, and especially his investigations into the etiology of infantile diarrhœa, are well known to the profession. It is therefore with the more surprise we learn from the *Leicester Advertiser* of May 30th that his retirement is due to the difficulties he has encountered at the hands of members of his authority, and has resulted from "the bullying and hectoring" he has been called upon to endure. The position of the medical officer of health is becoming increasingly difficult. He is expected to bring to the performance of his duties a greater technical knowledge, and is required to devote to them, for very inadequate remuneration, a considerable portion, if not the whole, of his time. He is also required by public opinion to protect the inhabitants of his district against disease, and to do so he must necessarily interfere with the vested interests of those who are but too readily allowed to assume the position of his employers. The duties of other officers of local authorities, clerks, surveyors, &c., do not cause them to excite the hostility of individuals whose interests are opposed to sanitary improvement, and their positions are therefore sufficiently secure. The medical officer of health is, however, differently circumstanced, and recent events have but too clearly shown the need for an improvement of his position. Unless the public mind is soon awakened to the importance of this matter, the public health service will deteriorate, and the public themselves suffer.

ŒDEMA OF THE GLOTTIS IN TABES DORSALIS.

ANY phenomenon may be met with in the course of tabes dorsalis; at least, this statement would seem to be a warrantable conclusion from known facts. We must not lose sight of the circumstance that accidental phenomena also exist and may occur in tabes dorsalis, as in any other disease, without any special significance. M. Huchard read at a recent meeting of the Société Médicale des Hôpitaux (*La France Médicale*, June 2nd) a paper on a case of Œdema of the Glottis following the administration of iodide of potassium in a patient the subject of tabes dorsalis. There was no history of syphilis or alcoholism, and no evidence of Bright's disease. The man was treated on account of the locomotor ataxy with four grammes of iodide of potassium per day. The treatment had to be suspended owing to the induction of iodism. After some days the medicament was given in smaller doses. This renewed treatment was followed by grave attacks of dyspnœa, which threatened suffocation. M. Gougenheim detected œdema of the arytenoid region by laryngoscopic examination. During one of the attacks the "interne" was obliged to perform tracheotomy. The patient ultimately did well. M. Huchard thought that the grave result was largely due to the influence of the iodide of potassium, whilst admitting that a sensory disturbance in tabes dorsalis may have played a part in the occurrence of the phenomenon. Chemical examination of the iodide of potassium showed that it was impure and contained a certain amount of iodates.

TREATMENT OF NEURALGIA BY NEUBER'S METHOD.

DR. SCHAPIRO recently read a paper, at the Medical Society of St. Petersburg, upon the results of researches on treatment of neuralgia by Neuber's method of hypodermic injections of a solution of osmic acid. His observations include eight cases of trigeminal neuralgia (three males and five females). The age of the patients varied from thirty-eight to sixty. In every case the disease was of a very severe type and of long standing. The result of the treatment was complete cure in five cases (three females and two males), great alleviation of the pain in two cases, and no success at all in one case (female). The number of injections made in each case was from one to twelve (twenty in one case), five to ten drops being injected every time. The duration of the treatment was from one to sixty days. Dr. Schapiro adopts a modification of Neuber's 1 per cent. aqueous osmic solution on account of the osmic acid soon undergoing decomposition in a watery solution. After a whole series of combinations, he concluded that an addition of glycerine to the watery solution prevents for a long time osmic acid from undergoing any change. In not one of the cases treated by him was an injection followed by any ill effect. The patients are now under the author's observation (two to six months after the commencement of the treatment).

VIVISECTION RETURN.

THE return issued by the Home Office containing the reports of the inspectors showing the number of experiments performed on living animals during the year 1884 appears to us to be highly satisfactory. It shows that a considerable amount of judgment and caution must have been exercised in the granting of licences, and this is indicated not so much by the paucity of persons holding licences as by the nature of the experiments and the purposes for which they were undertaken. We believe the Home Office takes a good deal of trouble in endeavouring to ascertain, not only from its inspectors, but from the most eminent men in science, whether the experiments proposed to be done by the applicant for a licence are such as are likely to be attended with useful or important results. Licences have been refused or the application allowed to fall through as the outcome of this advice from men fully competent to judge. Altogether 441 experiments were performed under forty-nine licences held in England and Scotland. Of these 218 were done under the full influence of anæsthetics, and the animal not being allowed to recover consciousness no pain would be felt. Of the remaining 223, 99 experiments simply consisted in inoculation with a morbid virus, and the pain caused at the time and the suffering experienced afterwards amounted to no more than ensues on ordinary vaccination; but of the 99 only 16 are reported as suffering afterwards, for the inoculation had no morbid effect in the majority. Twenty-four experiments were performed for the purposes of medico-legal inquiries in cases of suspected poisoning, resulting in death by tetanus of three frogs and six mice, which survived, however, only a few minutes. Ten other cases were experiments on the infection of fish with a species of fungus very destructive in certain rivers and streams; and five on the effects of immersion of fish in distilled water, which proved fatal to about thirty minnows and sticklebacks. In none of these cases could it be said that any appreciable suffering was inflicted. In seven cases in which the salts of ammonia were hypodermically injected, two are returned as having suffered pain, but of a very trifling character. Of the remaining 76 experiments, 47 required a simple operation, but this was always done under anæsthesia, and the after-effects, though in many cases resulting in partial paralysis, are reported as having been unattended with actual pain in any case. The report concludes by stating that the amount of direct or indirect actual suffering, as the result of physiological and therapeutical experiments performed in England and Scotland under the Act in the year 1884, was wholly insignificant. In Ireland the report states that only thirteen experiments were performed, and these were all of a painless character.

MEDICAL HONOURS.

OF the honours bestowed in connexion with Her Majesty's birthday a few have fallen to the share of members of the medical profession. Dr. Peter Eade, F.R.C.P.L., lately Mayor of Norwich, has received a knighthood; Dr. J. M. Cuningham, lately Sanitary Commissioner with the Government of India, has been appointed Companion of the Order of the Star of India; and Francis Day, Esq., Deputy Surgeon-General (retired), Medical Department, Madras, Companion of the Order of the Indian Empire.

SIR CHARLES ALEXANDER CAMERON.

THE profession as well as the public will learn with much pleasure that Dr. Cameron, the medical officer of health for Dublin, has received the honour of knighthood. It is stated that Dr. Cameron's services in the promotion of the public health have gained for him this distinction, and we warmly congratulate him upon being the first health officer who has had his services thus recognised. As a rule, honours of this character are bestowed upon medical men only for personal services to the Sovereign, the principal medical officers of the Army and Navy and very few others being exceptions. Sanitary service has, however, grown in public estimation, and we may hope to see in the future that the prevention of disease and saving of life effected through its means are thought to be not less deserving of recognition than other duties performed for the State.

CHOLERA IN EUROPE.

THE increase of cholera in the east of Spain and the invasion of fresh towns may be regarded as an indication that the year will not pass away without a repetition of some of the calamities which marked the appearance of the disease in France and Italy last summer. As yet there is no confirmation of the report that Marseilles is again the seat of the disease; but there can be no question of its prevalence in Madrid, and as the season progresses and the warm weather of June and July has had opportunity to exert its influence, we shall doubtless hear of the extension of cholera into more northern latitudes. Whether England may come within the area of its operations during the present year it is as yet too early to predict; but the fact that the second week of June has nearly ended without any sign of cholera in the direction which it usually follows before reaching this country is no criterion that we shall escape. The inoculations of Dr. Ferrán will doubtless excite more interest on the Continent than in England; our own defences against the disease are fortunately not only of a more trustworthy, but of a more permanent, character.

MIND AND MATTER RECONCILED.

MR. ROMANES, the Rede Lecturer at Cambridge this year, has hit upon an ingenious way of reconciling the antagonistic properties and interests of mind and matter. Finding himself in the midst of the cross fire between the spiritualists and the materialists in science, he proposes to put an end to the conflict by a synthetical process of reasoning, in which he seeks to show that the antithesis between mind and motion is phenomenal or apparent, not absolute or real. He does not think matter is the cause of mind or mind the cause of matter; in other words, motion does not always cause change or change always cause motion, but the two working side by side react and work out the chain of cause and effect together. This is a new development or application of the law of resultants, by which two forces acting in converging lines, or obliquely upon each other, give rise to a third or intermediate force, which is the result of their mutual reaction. We are therefore to believe that neither spiritualistic views of science are true nor materialistic views, but that truth is a mean of the two. We trust those who are harassed on the subject will find comfort in this new revelation of fact.

COCAINE IN "SNUFFLES."

DR. ZEMSHCHENKO has treated seventeen infants from two weeks to eleven months old with coryza by means of cocaine dropped into the nose. Two drops of a 2 per cent. solution were thus applied from four to six times a day with remarkably good results. In only one case was any increase of secretion observed. He has also made use of a 4 per cent. solution for older children. As, however, there is some risk of the solution being swallowed and producing vomiting, he finds it best to apply the cocaine by means of an ointment. In one case of suspected "snuffles" in a child three weeks old whose mother was syphilitic, the writer painted the nares with a 2 per cent. solution with a satisfactory result.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

THE Lord President of the Council has acknowledged the receipt of a letter from the Association, praying that the proposed new Charter of the College shall not be approved till the Fellows have had an opportunity of setting forth their views, which in many important respects differ from those adopted by a majority of the Council.

THE FRIENDLY SOCIETIES AND THE HOSPITALS.

THE Friendly Societies have recently made several demonstrations in support of the hospitals of London. Sometimes these take place on a Sunday, doubtless on the principle "the better day the better deed," and we fully recognise the goodness of the motive and of the service. But we are disposed to think that the bands would discourse their music more effectually for the purpose on some other day of the week—say on a summer Saturday afternoon.

DETECTION OF COPPER AND LEAD IN WINE.

A NEW method for testing the freedom of wines from cupric and plumbic salts has been put forward by H. Hager in the *Analyst*. The wine is mixed with half its volume of a clear solution of caustic soda which may contain carbonate. If the liquid remain clear after boiling, neither copper nor lead is present. A turbidity with colouration points to the presence of copper. About six cub. cent. of this solution are poured into a test tube, a piece of tin-foil introduced, and the whole heated for half an hour on the water bath. If lead and copper be absent, the foil remains perfectly bright; whereas if in the presence of a trace of one of these metals it becomes dull and grey for lead, and brown or brown-black for copper. This reaction may be applied to all cases when other metals are not present, and the solution remains clear after the addition of alkali.

SIR ANDREW CLARK.

THE profession will learn with regret that Sir Andrew Clark has been confined to bed for the past few days. But we are glad to be able to announce that, under the care of Dr. George Johnson, he is so far improved in health that he intends resuming his professional work on Monday. Sir Andrew will not take it ill from us if we venture to express the hope that he will use his indisposition as a sound excuse for refraining from working so hard.

DISARTICULATION OF THE HIP WITHOUT ANÆSTHESIA.

PROFESSOR GRUBE has recorded in the *Russkaya Meditsina* a case of disarticulation at the hip-joint for a large sarcomatous growth of the femur which weighed about sixty pounds, or nearly a third of the total weight of the patient. Distinct cardiac mischief being present, it was deemed necessary to avoid the use of an anæsthetic, also that of Esmarch's bandage. The patient was convalescent in seven weeks.

FATAL CASE OF PORRO'S OPERATION.

Il Morgagni of the 30th ult. relates the case of a primipara aged thirty-two, on whom Dr. Antonio Fibbi of Fabriano performed Porro's operation on April 15th. The patient had been in labour four days, and three days had elapsed since the membranes had ruptured. Delivery was blocked by a large tumour. The operation lasted a few minutes over an hour, and was unattended with complications. The pedicle was treated by the extra-peritoneal method. The patient died in collapse the day after the operation.

DIABETES IN THE DOG.

DR. PASQUALE FERRARO has recently (*Il Morgagni*, February and April, 1885) conducted a research on the comparative pathology of diabetes, in the anatomical institute of the University of Naples, under the direction of Professor Schrön. It results that diabetes mellitus may develop spontaneously in the dog, and gradually intensify until it becomes fatal. The etiology, clinical course, and histological anatomy of the disease, are similar in the human and canine species.

AT the Worship-street Police-court on the 9th inst., it was stated that the main drain in a certain road had been opened up for repairs by the Metropolitan Board of Works. The work had proceeded very slowly, and the drain had been fully exposed for the past three months, which was considered by the dwellers in the road to be an exceedingly long time for the necessities of the case. For many weeks the stench arising from the open drain had been unbearable. The magistrate, in reply to a gentleman who asked if anything could be done by the court to protect the inhabitants of the neighbourhood, stated his belief that the Board are liable to indictment for culpable delay, and advised that a solicitor be consulted.

THE King of Greece has recently conferred on Dr. Morris H. Henry, of New York, the Gold Cross, and created him an officer of the Royal Order of the Saviour. The honour was conferred for services rendered to medical science, on the recommendation of the Faculty of the University of Athens.

AT the forthcoming meeting of the British Medical Association, to be held at Cardiff on July 28th, 29th, 30th, and 31st, 1885, it is arranged that two subjects of considerable practical interest shall be discussed—namely, Mr. Treves (London) will introduce the subject of "Operative Interference in Intestinal Obstruction." Mr. Reginald Harrison (Liverpool) will read a paper introductory to a debate on "Bladder Tumours, their Diagnosis and Treatment." On the invitation of Dr. Bennett, the President of the Surgical Section, Professor Guyon of Paris has consented to be present and take part in the discussion on "Tumours of the Bladder."

AT the meeting of the Académie Royale de Médecine of Belgium, held on May 30th, Dr. Fleming, Principal Veterinary Surgeon to the Army, was elected a foreign correspondent. The Société Royale de Médecine et d'Hygiène Publiques has also elected him as a foreign correspondent. We are glad to learn that the health of Dr. Fleming is being gradually, though slowly, re-established, and that he is able to resume his important duties at the War Office.

A NEW edition of Dr. Murchison's work on Diseases of the Liver is in the press and will shortly be issued by Messrs. Longmans and Co. A new book by Dr. B. W. Richardson, entitled "The Work and Works on Health and Social Reform of Edwin Chadwick, C.B.," and a new work on "Children's Diseases" for popular use by Dr. C. West, will also be issued by the same firm in a short time.

ON the 4th inst. the medical officer of health for the Port of London obtained an order from the West Ham Police-court for the destruction of 463 carcases of sheep, 584 legs and shoulders of mutton, 70 pieces of beef, 20 bags of kidneys, &c., which were certified to be unfit for food. These formed part of the cargo of the steamship *Ruapehu.*

THE annual dinner of the Army Medical Department took place at the Holborn Restaurant on the 8th inst. Sixty-six officers, past and present, sat down, under the chairmanship of the Director-General. Sir William Jenner, who was to have been present as one of the guests, was unavoidably absent. A very pleasant evening was spent.

AN epidemic of cerebro-spinal meningitis appears to prevail in Dublin at present, and last week no less than eight deaths were recorded from the disease.

DR. WYCHERLY, High Sheriff for Cork, was knighted last week by Earl Spencer for his services in connexion with the recent visit of the Prince of Wales.

DR. JAS. J. L. RATTON, Surgeon-Major, Madras Army, has been appointed Professor of Surgery and Senior Surgeon at the General Hospital at Madras.

A CONVERSAZIONE will be held at the Royal College of Physicians, Pall-mall, on Wednesday, July 1st, at 9 P.M.

MR. VICTOR HORSLEY has been elected an Assistant Surgeon to University College Hospital.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The Prince of Wales has fixed Saturday, July 4th, for the ceremony of opening the Albany Memorial and other buildings of the hospital in Queen-square. The Prince and Princess Christian have signified their intention to be present, and the Archbishop of Canterbury will take part in the proceedings.

THE METROPOLITAN HOSPITALS.

As the result of inquiries we have recently instituted, we are able to state that the following metropolitan institutions are, amongst others, at the present time hampered in their sphere of usefulness by want of funds.

In the City Orthopædic Hospital there are three wards, recently furnished, with twelve beds, which cannot be used. The applications for admission to these wards on behalf of helpless little cripples are very numerous, and it is most distressing that they should have to be refused. The committee were three years appealing for funds to open and complete these additional wards. At the British Lying-in Hospital, Endell-street, some thirty more patients per annum could be received did funds permit. At the Royal Orthopædic Hospital there are five beds vacant for want of funds. At St. Thomas's Hospital three wards, containing ninety beds, are closed. The Committee of the Hospital for Consumption and Diseases of the Chest at Brompton were compelled, to avoid closure of a ward, to sell out £2000 of their funded stock last year. At the Paddington-green Children's Hospital many cases are daily refused admission for want of more beds. If funds permitted additional accommodation could be obtained. At the Royal Westminster Ophthalmic Hospital there are twenty-eight vacant beds. At St. Mary's Hospital there are twenty-six beds vacant. At St. George's Hospital many applicants are refused admission for want of accommodation. At Charing-cross Hospital there are thirty empty beds. In the report which was presented at the meeting of the Governors of the North-West London Hospital on March 27th the committee state that hitherto all the beds and cots have been occupied, but that now the stern necessity of partially closing the hospital, unless additional help is forthcoming, must be faced. At the Hospital for Epilepsy and Paralysis the burden of debt is so heavy, and the necessity of immediately meeting some of the largest and oldest claims so urgent, that unless the public will enable this institution to place itself forthwith in an honourable and satisfactory position, the committee cannot feel justified in increasing or perpetuating the existing state of indebtedness, and will most reluctantly feel it their duty to close the hospital against all but paying patients. What this will entail upon the suffering classes concerned can only be fully known to those who are intimate with the distressing kind of diseases dealt with in this institution, diseases which cause the profoundest suffering both of body and mind, and often preclude the possibility of self-support. At the Poplar Hospital for Accidents there are no beds vacant from want of funds, but the number of beds will have to be reduced from want of cubic space, if funds are not forthcoming to build additional accommodation. As it is, the number of beds is insufficient to meet the demands made upon them. At the Chelsea Hospital for Women the "Albert Edward" floor of twenty beds is entirely vacant for want of funds. At St. Thomas's Hospital, in addition to the empty beds mentioned above, two wards have been, through lack of funds, appropriated to the use of paying patients; and at Guy's, too, a similar expedient has for the same reason been adopted. At the London Hospital, where the number of in-patients treated last year was no less than 8015, the number of beds is [illegible], and the average fully occupied during last year was [illegible]. If the funds were larger more beds would be occupied, but there is no absolute rule that more than a certain number shall not be filled. In emergency, or in case of grave sickness, any person is admitted, it being trusted that the generosity of the public will supply the necessary funds. At this hospital there is a steadily increasing pressure as population increases, and as, indeed, it may be said with much regret the people become poorer. At the Evelina Hospital for Sick Children the committee have been compelled, in order to meet the deficit of the previous year, to trench upon the small invested capital of the hospital to the extent of £1000. Notwithstanding this sacrifice the balance-sheet shows a considerable deficit on the past year. At the London Lock Hospital and Asylum there are about fifty beds vacant from want of funds in the female department. At the London Fever Hospital, though no beds are unoccupied through lack of money, the isolation block, a most useful and necessary part of the establishment, is unused for that reason. At University College no beds are vacant, but the committee are obliged to depend upon the public and upon loans from their bankers to tide over their immediate pressing necessities. The debt of the hospital at the present time is over £7000.

It may be added that at St. Thomas's Hospital 79,019, and at the London Hospital 64,598 out-patients were treated last year, and that the total number of beds at the hospitals which derive benefit from the Hospital Sunday Fund is about 8000.

THE SANITARY CONFERENCE AT ROME.

SINCE our last issue the proceedings of the Technical Commission have been placed on a much more satisfactory footing. All the work is now submitted to sub-committees which hold morning sittings and prepare definite series of propositions, and these are then discussed and voted on separately by the full assembly. A record of the proceedings of last week's work will, therefore, be made more conveniently under the heading of each separate piece of work.

First came the report of a committee consisting of Drs. Eck, Hofmann, Thorne, Semmola, Koch, Proust, and Sternberg on Disinfection, and after discussion its provisions were accepted with only a few verbal alterations. The committee, desiring simplicity above all things, recommended for purposes of disinfection only three measures: (1) by steam under pressure, a system specially adapted to steamers; (2) carbolic acid or chloride of lime as chemical agents; and (3) efficient aeration; and they then entered into details as to the various methods of applying these agents to different objects and under varying circumstances. The report is one which is in the main fully in accord with the principles held in England, and it received the support of the English and Indian delegates.

Another sub-committee, consisting of Drs. Buonomo, Eck, Hunter, Koch, Lewis, and Zaëros Pacha, prepared a report on the measures to be adopted in connexion with the Pilgrimage to Mecca. The constitution of the committee will at once show that the interests of our great Indian Empire were well represented, and it is not too much to say that the report submitted was, up to the point of entrance of the pilgrims into the Red Sea, in the main an adaptation of the excellent sanitary regulations which have long been enforced in India. On some points India has not yet felt it right to interfere with religious convictions; but now that it appears from the statement of the Turkish delegate that the Mussulman creed is in no way affected by a requirement that no pilgrim should be allowed to start on his journey unless he can show that he possesses adequate means for the journey, it is much to be hoped that this very important condition will be universally acted on. Such a step will result in the saving of much life. As regards the measures to be adopted in the Red Sea, the delegates from this country assented to the propositions of the committee. It had several times been urged, as for example by Sir Guyer Hunter, that each country should be allowed to act on its own views as regards arrivals in its own ports, and hence where Turkish ports in the Red Sea were concerned, it was explained by Sir Joseph Fayrer that whilst he and his colleague thought that many of the restrictions imposed were needless and hence vexatious, yet that no opposition would be offered by delegates from this country. The assistance given to the Conference by Dr. Lewis's wide knowledge of this special subject was evidently of influence in securing a report which was accepted almost without modification.

Next came a report from a sub-committee as to the action necessary in ports of arrival, and, as in the case of the Red Sea Commission, we may congratulate ourselves that it contained *no English blood amongst its members. So hopelessly* had the committee tried to win both sides that the report was utterly rejected, and the committee were sent back to their labours. The next report they submitted was a substantial advance on the first. It gave free admission to a certain class of vessel even from so-called suspected ports, provided a medical inspection showed that after a certain length of journey there had been no illness, and that all needed measures of cleanliness, &c., had been observed. But if the journey had lasted less than ten days, all the crew and passengers had first to be kept under observation for twenty-four hours. As to infected ships, the sick were very properly to be landed and isolated, but this, too, was coupled with a regulation enjoining a period of from twenty-four hours to five days' observation for all on board if during any part of the voyage any person was suspected of having had cholera. This detention of healthy people was protested against by Dr. Thorne, who maintained that the English system of detaining only persons actually suspected of being ill for a period sufficient for the symptoms to develop themselves was ample. He was supported by all his colleagues from this country; but in view of the notions prevailing on the Continent, they were necessarily in a minority. Then came a genuine *fiasco*. What was to be done with the people who were landed? A committee, composed of such men as Drs. Koch, Baccelli, and Rochard, had actually prepared four propositions as to douching and bathing them. The ridicule cast by the Indian and British delegates on such a proposal secured them a strong following; and when, finally, Sir Guyer Hunter asked the committee to explain how they would bathe and douche nearly 2000 men, women, and children on board our great troopships, the committee thankfully accepted a suggestion that all the four propositions should be erased, and they were at once struck out as fit only for the waste-paper basket. As a general principle, the delegates from this country voted in the negative as to the imposition of quarantine of the healthy, whether under the name of observation or not, and then *declined to take part in any divisions that took place* as to the details relating to those measures.

Passing over certain matters of minor importance, the subject of the proceedings to be adopted after landing was dealt with by another sub-committee, composed of Drs. Sonderegger, Buonomo, Thorne Thorne, Eck, Ruysch, Grozs, and Hofmann. The report presented by this sub-committee was, like others where English and modernised views were represented, a valuable one, and, with the exception of the circumstance that it was regarded by Dr. Koch and others as entering into certain details which it would be better to leave to each country, it was practically accepted as a whole. English views were represented in its first paragraph, which claimed that the prevention of cholera was, above all things, to be dealt with by the sanitary development of a country and means of isolation, all of which should be ready in advance. This point was enforced by Dr. Thorne Thorne, who explained that in her action against quarantine England was not influenced by pecuniary motives, and that her authorities had since the date of the Vienna Conference spent over £27,000,000 in the interests of human life and health; and he showed by statistics of mortality how truly remunerative this expenditure had been. He added that it would be a lamentable day for England if she should ever think of changing such a system for the useless five days' quarantine which seemed to find such favour with the Conference. Following on a series of resolutions as to sanitary organisation, notification of first cases, &c., all of which are excellent, came certain details as to international trains, their inspection and cleansing, the provision of means of temporary isolation at stations, &c. Our delegates found no difficulty in accepting these on the ground that measures of precaution and cleanliness were always valuable; but Dr. Timothy Lewis explained to the Conference that the construction of railways in India had in no way altered the ancient lines of cholera diffusion, and Dr. Koch and others considered some of the details proposed as to train service quite superfluous. Sir Joseph Fayrer gave some valuable statistics as to the effect of sanitation in India, urging the Conference to put their trust in these rather than in detailed regulations as to traffic; and he was supported by Sir Guyer Hunter, who reverted to details bearing in the same direction which he had given at a previous sitting.

The work of the Technical *Commission came to an end on* Saturday last, and since the full Conference did not again assemble *till* Thursday, the Government have asked the delegates to be the guests of the State during a visit to Naples, special trains, and a man-of-war in the bay, being provided by the Government.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5892 births and 3497 deaths were registered during the week ending June 6th. The annual death-rate in these towns, which had been equal to 21·1 and 21·0 per 1000 in the preceding two weeks, further declined last week to 20·5. During the first nine weeks of the current quarter the death-rate in these towns averaged 21·8 per 1000, against 22·6, the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 10·0 in Brighton, 10·9 in Norwich, 13·2 in Wolverhampton, and 13·5 in Halifax. The rates in the other towns ranged upwards to 25·5 in Preston, 26·3 in Birkenhead, 31·0 in Newcastle-*upon-Tyne, and 33·6 in Manchester. The deaths referred to* the principal zymotic diseases in the twenty-eight towns, which had been 510 and 487 in the previous two weeks, rose to 521 last week; they included 224 from measles, 130 from whooping-cough, 32 from diarrhœa, 37 from small-pox, 44 from "fever" (principally enteric), 23 from diphtheria, and 31 from scarlet fever. No death from any of these zymotic diseases was recorded last week in Brighton, Norwich, or Halifax; whereas they caused the highest death-rates in Sheffield, Manchester, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Birkenhead, Sheffield, Manchester, and Newcastle-upon-Tyne; from whooping-cough in Cardiff, Plymouth, and Blackburn; from scarlet fever in Leicester, Sunderland, and Cardiff; and from "fever" in Portsmouth and Newcastle-upon-Tyne. *The 23 deaths from diphtheria in the twenty-eight towns included 15 in London and 2 in Hull. Small-pox* caused 59 deaths in London and its outer ring (exclusive of 23 recorded in the metropolitan asylum hospital ships and camp at Darenth), 2 in Manchester, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had steadily increased in the preceding ten weeks from 830 to 1389, declined to 1201 at the end of last week; the admissions, which had ranged between 354 and 211 in the previous five weeks, fell to 180 last week. The Highgate Small-pox Hospital contained 68 patients on Saturday last, 19 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 291, 305 and 302 in the preceding three weeks, declined last week to 290, but exceeded the corrected weekly average by 20. The causes of 90, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, and Brighton, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, Blackburn, and Bolton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·4, 21·2, and 20·5 per 1000 in the preceding three weeks, rose again to 21·8 in the week ending 6th June, and exceeded by 1·3 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·2 and 16·5 in Leith and Aberdeen, to 25·1 in Glasgow and 25·4 in Greenock. The 532 deaths in the eight towns showed an increase of 32 upon the number in the previous week, and included 23 which were referred to whooping-cough, 16 to diarrhœa, 15 to measles, 11 to scarlet fever, 6 to diphtheria, 3 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 74 deaths resulted from these principal zymotic diseases, against 67 and

59 in the preceding two weeks. These 74 deaths were equal to an annual rate of 3·0 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 22 and 27 in the preceding two weeks, declined again to 23 last week, which included 12 in Glasgow, 6 in Edinburgh, and 3 in Dundee. The 16 deaths attributed to diarrhœa showed an increase of 6 upon the number in the previous week, but were equal with the number in the corresponding week of last year. The deaths from measles, which had been 19, 15, and 11 in the previous three weeks, rose again to 15 last week, of which 14 occurred in Glasgow. The 11 fatal cases of scarlet fever showed a considerable increase upon the numbers in recent weeks, and included 4 in Glasgow, 2 in Edinburgh, 2 in Leith, and 2 in Paisley. Four of the 6 deaths from diphtheria were returned in Glasgow. The 3 deaths referred to "fever" showed a decline from recent weekly numbers, and were considerably below the average number. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 107 and 87 in the preceding two weeks, rose to 126 last week, and exceeded by 36 the number returned in the corresponding week of last year. The causes of 74, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 35·0, 31·2, and 25·7 per 1000 in the preceding three weeks, further declined to 23·1 in the week ending June 6th, and was considerably lower than in any previous week of this year. During the first nine weeks of the current quarter the death-rate in the city averaged, however, no less than 30·8 per 1000, the mean rate during the same period not exceeding 20·5 in London and 18·6 in Edinburgh. The 156 deaths in Dublin last week showed a further decline of 18 from the high numbers in recent weeks, and included 9 which were referred to measles, 2 to whooping-cough, 2 to diarrhœa, 1 to scarlet fever, 1 to "fever," and not one either to small-pox or diphtheria. Thus 15 deaths resulted from these principal zymotic diseases, against 34, 33, and 21 in the preceding three weeks; these 15 deaths were equal to an annual rate of 2·2 per 1000, the rate from the same diseases last week being 3·2 in London and 2·7 in Edinburgh. The fatal cases of measles in Dublin, which had been 17 and 13 in the previous two weeks, further fell to 9 last week, and were fewer than in any week since the middle of February last. The deaths from "fever" and from scarlet fever also showed a further decline from recent weekly numbers. Only one inquest case and 1 death from violence were registered within the city. Nearly a quarter of the deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a further considerable decline from the numbers in recent weeks. The causes of 26, or nearly 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Honorary Brigade Surgeon W. F. Ruttledge, now on retired pay, has been appointed to take charge of the 1st Infantry Brigade at Aldershot.

Thirty-five officers undergoing a course of instruction in Medical Staff Corps drill, &c., at Aldershot are attached for a course of instruction in riding, 20 to the Cavalry Brigade, 10 to the Royal Artillery, and 5 to the Commissariat and Transport Corps.

War Office.—The Secretary of State for War has appointed Howard W. Hunt, Esq., M.R.C.S., to be Visiting Surgeon for Shorncliffe, under the Contagious Diseases Acts, 1866 to 1869, vice J. W. Howard, deceased.

Army Medical Staff.—Brigade Surgeon W. O'Halloran has retired on temporary half-pay; Surgeon John Sydney Langton resigns his commission.

Admiralty.—The following appointments have been made:—Fleet Surgeon Garland W. L. Harrison, to the *Excellent*; Fleet Surgeon Daniel O'Connor, M.D., to Devonport Dockyard; Staff Surgeon Fleetwood Duckle, M.D., to the [illegible]; Surgeon James Porter, M.B., to the *Pembroke*; Surgeon John Cashin, to the *Duncan*; Surgeon Timothy J. [illegible], M.D., to the *Royal Adelaide*.

Yeomanry Cavalry.—Cheshire: George Harrison, Gent., to be Surgeon.

Artillery Volunteers.—1st Northumberland and Sunderland:—William Henry Besant, Gent., to be Acting Surgeon.

Rifle Volunteers.—1st Bedfordshire: Acting Surgeon Henry Frederick Holland, M.D., to be Surgeon.—10th Lanarkshire (Glasgow Highland): Angus Macphee, Gent., M.D., to be Acting Surgeon.—2nd Sussex: Walter Samuel Simpson, Gent., to be Acting Surgeon.—1st Volunteer Battalion, the Prince of Wales's Own (Yorkshire Regiment): Acting Surgeon Alfred Baker to be Surgeon.

Correspondence.

"Audi alteram partem."

ADDISON'S DISEASE.

To the Editor of The Lancet.

Sir,—Dr. Wickham Legg, in his interesting communication to your journal on Addison's disease, says that the theory which makes it a tubercular affection of the supra-renal bodies must be given up. I am somewhat at a loss to know whether Dr. Legg is arguing solely against the opinion that the change *usually found in the adrenals is strictly* tuberculous, or whether he is denying the truth of the usually received theory of the nature of the disease, and which in common parlance is often spoken of as tuberculous. If Dr. Legg writes merely to maintain the former, I agree with him, but if the latter, I am sorry to find myself at variance with him. Addison's first published cases were examples of what was then called tuberculous disease, but the author did not state that this condition was characteristic of the disease; it was left for myself, by an accumulation of a large number of cases, to insist upon the fact, and therefore reduce morbus Addisonii to a very strict definition as regards the changes in the organs. I maintain that the disease was primary and of one kind. This view I further propounded in the article on Morbus Addisonii in Reynolds's System of Medicine. It was shortly as follows:—

In Addison's disease there is found a total destruction of the adrenals, the consequence of a primary or essential disease, which is comparable with that of the primary affections of other organs. In considering the diseases of other double organs, we do not refer to their accidental implication by new growths, but to the slow implication of their structure by a primary morbid process. Indeed, I know of no instance where both lungs would be involved to their destruction without a trace of similar disease elsewhere, or of a uniform implication of the kidney, and the rest of the body free. Were I, indeed, to meet with such cases, I should regard the disease as one essentially primary. In the same way, I have no knowledge of any adventitious disease attacking both adrenals to their destruction, and showing no trace of its existence elsewhere. From what I know of pathological processes, it seems to me that a disease involving the entirety of both adrenals, and leaving the rest of the body untouched by it, must be a primary affection of those organs. It would therefore not be tubercular. This fact, too, would also imply more—that the disease would be of a similar nature to that found in the other viscera, especially the double organs. Now, the slow process which gradually involves the parenchymatous structures is usually called inflammatory, and the same term may be with equal truth applied to the process which destroys the adrenals. The chronic primary affections of the lungs are of a similar nature to those seen in cirrhosis of the liver, and called interstitial hepatitis, or in the kidney, and called interstitial nephritis, or in the spinal cord, and styled sclerosis, the process being modified according to the structure of the organ. In the adrenals the organs may sometimes be found increased to three or four times their ordinary size, owing to the production of an albuminous material composed of fibre and cell elements. At a later period this material undergoes caseation, cretification, and softening, and at the same time the mass is much reduced in size, so that in very long-standing cases of morbus Addisonii, nothing but a few nodules of cheesy matter may be found, or a few grains of chalk, or perhaps a thimbleful of creamy fluid. In looking at these cases it is evident that a few more months would have seen the whole of this morbid material disappear. This sometimes occurs, as in one of the best-marked cases of the disease which I have seen, the one referred to by Dr. Legg as presented to the Pathological Society by Dr. Eastes, and several other similar cases have been reported. I do not look upon this termination as surprising, but as inevitable, and I see no reason why the same should not occur in other organs if they were nonvital. The adrenals are not vital organs in the ordinary sense, seeing that persons live without them for many years, although it is equally true that when diseased they bring about death in a slow and insidious manner. We see the liver waste in the cirrhotic state, and, as regards the kidneys, we sometimes find them in Bright's disease reduced to their minimum size compatible with the existence of life. In the case of the thyroid, the glandular structure may altogether disappear, and as a result of inflammation of the testes every trace of the organ may have gone.

I would say therefore, in conclusion, that if Dr. Legg merely wishes to maintain that the affection of the adrenals so usually found in morbus Addisonii is not tubercular, I cannot but agree with him, having always insisted upon the same fact; but if his paper is written with the object of contravening the views which I have just stated, that the disease of the organs is essentially of one nature, and of that character which has mistakenly been called tubercular, then I am at variance with him. From a study of a large number of cases over many years I have formed the opinion which I have given, and I regard the cases which Dr. Legg has described as highly confirmatory of this view. His paper and remarks thereon are very interesting, and the truth can only be arrived at by a thorough criticism of this kind, but my conclusions drawn from his illustrations are, I am sorry to say, totally different from Dr. Legg's. He would say that, inasmuch as we sometimes see cases of Addison's disease where no trace of the adrenals can be found, the usual theory of their so-called tuberculous nature must be given up. I, on the contrary, would say that the total absence of the organs in very chronic cases proves to my mind indisputably that such process (so-called tubercular) and none other must have led to it.

I am, Sir, yours obediently,

Grosvenor-street, June, 1885. SAMUEL WILKS.

TREATMENT OF ACUTE PERITONITIS BY ABDOMINAL SECTION.

To the Editor of THE LANCET.

SIR,—The abstract of Mr. Treves' paper on this subject, given in THE LANCET of March 14th, gives doubtless a complete view of that gentleman's opinions and action in the particular case narrated, though it does not contain anything more than a slight allusion to a previous work on the subject; but it is quite enough to convince me that he has taken an insufficiently wide grasp of this important advance in abdominal surgery, and that he is not aware of the fulness of the reception which has already been accorded to the practice which he suggests as being proper for cases of acute general peritonitis. So far as I know, the first record of an operation performed deliberately on account of acute peritonitis was proposed and carried through by Dr. Wiltshire in 1868. An account of the case will be found at page 294 of the recent edition of my book on Diseases of the Ovaries, where I say: "I think sufficient praise can hardly be given to Dr. Wiltshire for his courage in performing the operation under such urgent conditions, and it is not too much to say that to his success in this case we owe a new departure in the practice of abdominal surgery by which operations under acute symptoms are undertaken, and apparently with results as satisfactory as those obtained in cases free from emergency." This has long since become the established practice, and I should think that some scores of cases are now on record where it has been completely and successfully adopted.

It is now some twelve years since I myself for the first time followed Dr. Wiltshire's example, and after I had done so I naturally asked myself the question, Why should I limit my operations to cases of peritonitis in which the disease is complicated by an ovarian tumour? Since that time I have never allowed a patient to die of peritonitis without opening the abdomen, if I could obtain the consent of my colleagues and the patient's friends, and that consent has very rarely been withheld. The results of the great majority of these operations have been published in detail under various headings, because it has rarely been found that the cause of the peritonitis could not be ascertained, and under the head of the cause each case has been recorded, leaving only two instances in which the cause was not ascertained, and which were therefore recorded as operations for acute peritonitis. I have not made an accurate research into my record for the purpose of this paper; but I believe my statement is nearly correct when I say that I have opened the abdomen forty-four times on account of the presence of peritonitis, and that the operation has been completely successful in forty-one of the cases.

This leads me to say that Mr. Treves' case is open to a criticism on two points to which I desire to draw emphatic attention; because, though I give him most willingly all credit for the success of the case so far as it has gone, I *think that success is due more to good luck than to good* guidance. He tells us the patient was admitted to the hospital "on Jan. 21st, suffering from chronic pelvic peritonitis following severe gonorrhœa." Sufficient has been put upon record concerning this condition to make it perfectly certain that this patient was suffering from pyosalpinx; and if any further proof is needed, we have only to pass on two sentences, and find that the abscess was on the left side, where it always is if pus exists at all in the Fallopian tube. The case was clearly one of antecedent rupture of a suppurating tube, with the formation of a limited abscess, the secondary rupture of this abscess being the cause of the peritonitis. The first point of criticism is, therefore, that this patient ought to have been operated upon within three or four days of her admission to the hospital, and should not have been allowed to go on till Feb. 26th merely for the purpose of running the gauntlet of an attack of acute peritonitis. The second point of criticism is that Mr. Treves has not—at least he does not tell us that he has—removed the Fallopian tube. If the rent, which undoubtedly occurred in it, was sufficiently large and satisfactory to allow for a vent and the healing of the tube, then perhaps the patient may escape without further trouble. But the experience of those of us who have had a large number of these cases to deal with is that a case so incompletely treated as this will simply be the subject of further trouble by-and-by, when the removal of the tube will be a difficult and risky proceeding.

I am, Sir, your obedient servant,

Birmingham. LAWSON TAIT, F.R.C.S. Eng.

AURAL EXOSTOSES.

To the Editor of THE LANCET.

SIR,—In answer to Mr. Dalby, I beg to state that I have never claimed any originality for the operation for the removal of aural exostoses. On the contrary, I have always mentioned the name of Dr. Arthur Matthewson[1] of Brooklyn, New York, as being entitled to all the credit that is due in this matter. Dr. Matthewson some years ago kindly sent me his pamphlet, in which he carefully describes his first case (1876), and from this paper I got my idea of the operation.

Mr. Dalby says that from 1874 he has employed the drill, and in 1876, in THE LANCET, he states, "The operation consists in grinding the bone away, and the most satisfactory appliance for this purpose I find to be the drill which is in common use among dentists." But he has not published any cases for our guidance describing the details of the operation, and I was certainly under the impression that Dr. Matthewson's was the first case. That I am not singular in this opinion, I would refer to the authors[2] indicated below, who in this connexion never mention Mr. Dalby's name, for they doubtless have all of them missed so brief a notice of what is really a tedious and capital operation.

In the last edition of Mr. Dalby's work, published this year, he tells us nothing that adds to our knowledge, except, he says, that at the International Medical Congress held in London, Aug. 1881, "I called attention to the fact that in a very large proportion of these cases the subjects of the growths had been for many years addicted to sea-bathing." A fact that I was the first to demonstrate at least six months before.[3]

ON ACQUIRED IMMUNITY FROM INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—While Dr. Sternberg, in his paper entitled "What is the Explanation of Acquired Immunity from Infectious Diseases?" in THE LANCET of April 11th and 18th of the current year, does not directly claim originality for the "vital resistance theory," a claim is at least implied by his statement that his work antedated that of Grawitz and Salmon. Dr. Sternberg's paper was read at the meeting of the Clinical Society of Maryland held on Dec. 5th, 1884. In it he bases his claim to priority upon a paper published in the *American Journal of the Medical Sciences*, April 1st, 1881. In the discussion which followed, I had the honour to show that at the annual meeting of the Medical and Chirurgical Faculty of Maryland held in April, 1875, I had read a paper (published in the Transactions of the Faculty for that year) in which the theory of immunity expressed by Dr. Sternberg in his paper was distinctly and explicitly propounded. This was publicly admitted by Dr. Sternberg at the meeting at which his own paper was presented. As Dr. Sternberg, while mentioning those who followed him, has neglected to refer, even in a footnote, to my publication antedating his own by six years, I beg that you will favour me by printing the enclosed extract from my paper, a reprint of which I have also the honour of sending.

I am, Sir, your obedient servant,
J. E. ATKINSON, M.D.

University of Maryland, Baltimore,
May 8th, 1885.

Extract.

"It has been stated that all the parts of the tissues of the body whose molecular motion was such that the consequence of their union with the contagious particles was to degrade them until they were unfit for their normal functions were thrown off from the body, and that there were left behind only such portions as were able to repel the contagia, or, having united with them, were able, while undergoing a certain modification themselves, to also modify the life of the contagia, so that the union would result in matter, somewhat altered it is true, but not to such an extent as to interfere with the performance of proper normal function. The body will thus have gotten rid of all matter capable of being degraded by the contagium of the given specific fever. In the course of the subsequent nutrition of this individual, there must be a constant and almost unvarying supply of new material introduced from without. It has been seen that within the system, and endowed with life, this material is termed protoplasm. Now the mere fact of proteinaceous compounds gaining access to the circulation does not confer upon them the properties of this protoplasm. ... ... On the contrary, it must be that, as these matters enter the circulation, they may not attain the dignity of protoplasm until life shall have been conferred upon them by their incorporation with the protoplasm already existing in the body, with the buds and gemmules split off from the larger masses, and which, thus nourished, increase in size and develop the properties of their progenitors. Understanding, then, that these buds and gemmules are all descended from the protoplasm that has already resisted or been modified by the especial contagium particle, it is perfectly evident that they and their descendants must possess the same qualities of resistance. At the same time, it will not be difficult to imagine that this condition, being one opposed to the perfectly normal life of the cells of the body, may after a time, in consequence of a steady and persistent tendency to regain the condition enjoyed before infection, be receded from, and the individual again acquire his susceptibility to the same eruptive fever that he has already experienced. In the same manner may we account for the fact that the occurrence of the diseases in the parent does not necessarily or usually confer immunity upon the offspring; that a certain protection is conferred we know, since the eruptive fevers almost always produce their most dire effects upon virgin populations. The history of epidemics in the Pacific Islands exemplifies this. It is even probable that several diseases, the causes of dreadful mortality in centuries gone by, have disappeared in consequence of an immunity gradually inherited. In spite of this, however, it is very probable that in the reproductive processes the inheritance of perfectly normal molecular motion tends to reassert its superiority over that of a recently acquired modified motion, and that it returns to the mode of life that appertained to the parent previous to the occurrence of the eruptive fever, just as the parent would return, and sometimes does, were his vital processes as active."

HEALTH ASSURANCE ASSOCIATIONS.

To the Editor of THE LANCET.

SIR,—As imitation is the sincerest flattery, I suppose I ought to feel flattered by the fact referred to in your leading article of the 30th ult., that no fewer than three of these associations have been started within the last few months. I do not feel flattered however, I am simply grieved—not because of the fact that these societies have adopted my scheme as far as they can, and one of them has even appropriated the name which I have given to the system without the slightest acknowledgment, but at the misapplication of the scheme, and at the further loss and damage which the profession in particular is sure to suffer if these associations are to be allowed to grow.

On what grounds are my objections based? On these:—The formation of an "Association" for the working of health assurance is not only absolutely unnecessary but positively mischievous—first, by increasing the cost of working the system; and, secondly, by taking the control of the fees out of the hands of the medical practitioner. These are two of the evils of the provident dispensaries, and in these new associations they will be greatly magnified.

First, the cost of working. Where are the expenses of rent of offices, salaries of the secretary and clerks, commissions of agents, and other disbursements to come from? Is it not clear that if the fee charged to an assurer for medical attendance be 20*s*. per annum, not more than 15*s*. will find its way into the pockets of the medical attendant? Why should medical fees be thus divided and the profession or the public robbed?

Secondly, the doctor's loss of control over his fees. That this is an evil only too real, the medical officers of provident dispensaries and the various amalgamated friendly societies can bear witness; but the evil is trifling in amount compared with what it will be if the promoters of these aggressive companies are to have their way. One would have thought that the profession had already learned a lesson on this point which would have made it jealous of its rights and duties for the future; but it seems the lesson has not yet been severe enough. I have elsewhere shown that the one remedy *par excellence* for the evils of clubs and many other evils besides is health assurance—not health assurance "associations." For the working of life assurance and the various schemes of assuring against the losses of accident and sickness, associations are really necessary; but a serious blunder is committed if it be assumed that health assurance can be advantageously worked in the same way. Nor does the blunder affect the medical profession alone. One of the great advantages of health assurance is that the patient is brought into an intimate and friendly relation with his client, in whose health he becomes interested from the moment when the first fee is paid, and he has many and regular opportunities—at the periods of payment for example—of seeing the assurer and his dwelling, observing his state of health, advising him thereon, and detecting the beginnings of disease. Is this a picture of the state of things likely to obtain under a middleman, *alias* an "association"? If the medical profession persists in its policy of indifference and *laissez-faire*—which has already proved so disastrous—in matters so nearly concerning its best interests and those of the public, of whose health it ought to be the custodian, the punishment will be as certain as it will be richly deserved.—I am, Sir, yours truly,

---

"SINGULAR MEDICAL EVIDENCE."

To the Editor of THE LANCET.

SIR,—Under this "singular" heading I was astonished to see a notice in your issue of June 6th of an article which appeared in the *Echo* regarding the medical evidence given at an inquest held in Poplar on May 28th. I may state briefly that the *Echo* has given an entire misrepresentation of the whole matter. In the first place, there was no "fatal fight at Poplar" at all; and, in the second place, I did not say what in the account referred to I was reported to have said.

The facts are simply these:—An old man was peacefully driving a barrow along the road, when a drunken man, an utter stranger, rushed up, struck him heavily under the jaw so that he fell backwards, striking the back of his head with great violence on the ground, and was picked up dead. On making a post-mortem examination, I found the cause of death to be cerebral hæmorrhage from the violence of the concussion, well-marked atheroma of the vessels greatly predisposing to the result. I found also advanced renal disease and cardiac hypertrophy. In describing the skull and brain appearances, I mentioned that on removing the skull-cap quite an unusual amount of thick fluid *escaped* from the sinuses, &c. I could not measure it, as most had oozed out, but my assistant and myself roughly estimated there might be nearly a pint; however, I could form no exact estimate of the amount. I subsequently went on to describe the usual signs of cerebral hæmorrhage which I found.

I can only ascribe the insertion of the article in question to lack of sensational matter, but I do not feel particularly ambitious to be chosen as the subject of such fictitious reports.

I am, Sir, your obedient servant,

W. MURRAY LESLIE, M.B., C.M.Edin.

Cubitt Town, E., June 10th, 1885.

⁂ We do not see that our correspondent has any material ground of complaint, as our remarks practically agree with his own version of the matter.—ED. L.

MANCHESTER.

(*From our own Correspondent.*)

CHARITY ORGANISATION IN MANCHESTER.

AT the last meeting of the Manchester Statistical Society a paper of considerable interest to the profession was read by Mr. F. Scott upon Charity Organisation in this city. He stated that the total sum received annually by forty-two voluntary institutions was nearly £150,000, and that, comparing this sum and the machinery provided therewith, the total results were much below what they might be if the various charities were working more or less together. He pointed out that this was especially the case with the hospital charities. Economical administration would be largely promoted by co-operation. He suggested that a kind of federal council should be formed, made up of representatives elected by the subscribers to the different institutions, which council should be subdivided into committees and subcommittees, to superintend the details of the working of each charity, such committees to report to and be controlled by the general council, whilst the main body would legislate and control all matters of common interest. The debate was carried on by a number of gentlemen interested in our charities, amongst whom was the Dean of Manchester, who gave it as his opinion that our organisations were worked too much on the lines of competition, that by too much subdivision there was a loss of power, and that much good would be effected by more combination amongst them.

THE FORTHCOMING CONFERENCE AT BLACKPOOL.

At a preliminary meeting of representatives of Boards of Guardians, held last week in the Town Hall, to consider the programme for the conference to be held at Blackpool, the Lunacy Laws Amendment Act was under discussion, and it was noted with satisfaction that the Lord Chancellor had made several important amendments in the Bill, which had brought it into more harmony with the views of various boards of guardians who had made representations concerning the unworkable nature of some of the clauses. There has lately been some little trouble in dealing with pauper lunatics here; hitherto it has been the habit of the magistrates to remit pauper lunatics to the workhouse, where they were kept for a time under observation, and, if confirmed lunatics, were then removed to an asylum. The master of the Manchester Workhouse has, however, lately notified to the guardians that he must in the future refuse to admit lunatics to the workhouse, it being illegal to do so, nor have the magistrates power to order them there. Amongst the subjects set down for discussion at the coming conference at Blackpool is that of hospital accommodation for infectious diseases, and as most of the rural sanitary authorities are formed from boards of guardians, it is one that may be discussed there with considerable advantage.

THE SALE OF HORSE-FLESH.

For some little time past disquieting rumours have been abroad as to the illicit sale of horse-flesh, and the subject has occupied the attention of both the Salford and Manchester Town Councils. At the last meeting of the latter, it appeared that certain regulations which the Market Committee had contemplated putting in force with a view to check this imposition on the poorer classes had failed to receive the sanction of the Local Government Board, on the ground that the power sought by the Corporation was not merely an amendment or addition to any existing Act, but was virtually new legislation, for which there was no precedent.

DEATH OF DR. THORBURN.

Again we have to mourn the loss of one of the leaders of the profession in the comparatively sudden death of Dr. Thorburn. His loss will be felt among a large number in and around Manchester; his genial kind-hearted disposition had endeared him to students, colleagues, and patients. By his death another gap has been made in the professorial staff at Owens College, where he occupied the chair of Obstetrics and Diseases of Women. At the infirmary a vacancy is also caused, where he held the post of Obstetric Physician. It had for some time been known to his friends that he suffered from heart disease, but none suspected the end was so near. Pulmonary thrombosis suddenly laid him low and he died in little more than a week from the first onset The continuation of the course of lectures he was engaged on at the College has been arranged to be completed during the present session by members of the staff of St. Mary Hospital.

SIR HENRY ROSCOE.

It is not improbable that ere long the College will lose the active services of another old and valued professor, Sir Henry Roscoe, who has been asked to become a candidate for parliamentary honours at the ensuing general election Should he be elected, his time available for College work will necessarily be very limited; but his presence in the House of Commons would undoubtedly be a great acquisition to the scientific element, which at present is too scantily represented there.

SMALL-POX.

The outbreak of small-pox which occurred here some few weeks since has not assumed very large proportions, and so far the authorities have had no difficulty in providing sufficient hospital accommodation. Up to the present time the cases have chiefly arisen in Manchester, and the bulk of these in the northern part of the city. Very few cases have as yet occurred in the neighbouring borough of Salford.

At the last meeting of the Chorlton guardians tenders were received for the extension of their hospital at Withington, to the amount of nearly £15,000.

Manchester, June 8th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE CATHEDRAL NURSING SOCIETY.

THE second annual meeting of the Cathedral Nursing Society has been held. This Society does a large amount of good in a quiet manner amongst the sick poor in the way of supplying nurses, suitable invalid food, and appliances necessary in the sick-room; and this is done irrespective of religious denomination—principally, too, on the recommendation of medical visitors. It has dispensed during the past year 5255 pints of beef-tea, 8460 pints of milk, 523 chop dinners, 342 fish dinners, and 1621 meat dinners. The number of persons nursed has been 1171; supply of night-nurses, 195. Most of the persons nursed have been out of work during the winter. In some cases the patients cheerfully contributed to the funds of the Society.

A MEDICAL MAN ATTACKED BY A HORSE.

Our papers give a circumstantial account of a savage attack on a medical man by a horse. Dr. Richards, assistant to Dr. W. Renton of Shotley Bridge, Durham, in attempting to mount his horse on leaving a patient's house, the animal resisted, and attacked him in a savage manner with its teeth. Dr. Richards struck it several blows with his stick, but, notwithstanding, the animal succeeded in thrusting him into an enclosed yard, where it again attacked him in a most vicious manner, tearing his clothes and fracturing his arm. A passer-by rushed at the horse with a heavy block of wood, and succeeded in beating it off. I am glad to hear that, with the exception of the fracture, Dr. Richards's injuries are not serious.

THE MEASLES EPIDEMIC IN THE NORTH.

The course of the epidemic of measles in Sunderland shows a steady waning, but has made progress in Newcastle. During the last month (May) the increase has been very marked in the latter town, while in Sunderland during the same time there has been more than a corresponding decline. Some of the large towns on the Tyne, such as Jarrow, as well as the smaller mining and manufacturing villages, have suffered very severely. Lately the weekly mortality of Sunderland from all causes has fallen to 18·6 per 1000.

LUNATICS IN HARTLEPOOL WORKHOUSE.

At the last meeting of the Hartlepool Board of Guardians, Mr. Cleaton, one of the Commissioners in Lunacy, sent in a report upon his recent visit to the workhouse. It set forth that there were eighteen imbecile and insane patients, nine of each sex; one admitted on April 23rd was in a strait waistcoat, and was suffering from acute insanity, and quite unfit to be under workhouse care. A woman suffering from acute mania, it was pointed out, was scarcely fit to be in a workhouse. Another case required constant watching. The accommodation for these classes was quite inadequate. The clothing, too, of the imbeciles was unsatisfactory. The Local Government Board also sent some extracts from the report of the Poor-law inspector complaining of the bedding of the female imbeciles. The clerk to the guardians had been directed to state in reply that there were now no more cases than the wards were certified to accommodate.

LUNACY APPOINTMENT.

The Lord Lieutenant of Ireland has appointed Dr. A. Finegan to succeed Dr. Norman as resident medical superintendent of the District Lunatic Asylum at Castlebar. Dr. Finegan is well known in the north of England, having been for some time assistant medical officer in the Northumberland County Asylum at Morpeth.

Newcastle-on-Tyne, June 10th.

EDINBURGH.

(*From our own Correspondent.*)

SPECIAL MEETING OF THE MEDICO-CHIRURGICAL SOCIETY.

A NEW departure in the meeting arrangements of this Society was made recently, when a special meeting was held for the exhibition of pathological specimens and the discussion of clinical cases of special interest. The meeting was largely attended, and the proceedings were of an unusually interesting nature. At the close, the President congratulated the Society upon the success of the experiment, and announced that a series of similar meetings will be held in future alternately with the ordinary meetings.

THE METHOD OF COMPRESSING THE SUBCLAVIAN ARTERY.

Dr. Joseph Bell exhibited the upper extremity of a patient in whose case amputation had been performed for extensive sarcomatous disease of the scapula. The hæmorrhage had been controlled by a method recommended to him by Professor Chiene, in which a curved steel skewer was passed from above downwards behind the subclavian trunks, and brought out in front through the pectoral muscles. Pressure was exerted on the vessels by an elastic tube applied as a figure-of-8 over the anterior part of the region transfixed, a firm pad intervening between the elastic tubing and the patient's skin. The method is similar to that used by the late Professor Spence in the case of the femoral artery in amputation at the hip-joint. In this case Dr. Bell found the method perfectly satisfactory, as the limb was removed with the loss of but two ounces of blood.

ULCERATIVE ENDOCARDITIS.

Dr. Byrom Bramwell showed a series of microscopic sections of various tissues from cases of acute ulcerative endocarditis, stained by Gram's method. In all there was a most admirable demonstration of the micrococci present in this disease. Dr. Bramwell mentioned that some cultivation and inoculation experiments made in connexion with these cases had yielded as yet no positive results; but that he had little doubt as to the infective nature of the disease.

PARIS.

(*From our Paris Correspondent.*)

THE INTERNATIONAL SANITARY CONFERENCE.

FROM a conversation I have had with an English physician who has just come from Rome, where he had been to take part in the proceedings of the International Sanitary Conference, I have learned, but not with astonishment, that the Conference may probably break up without having materially increased our knowledge of the nature and prophylaxis of cholera, as the majority of the foreign members seem to be antagonistic to their English colleagues, for almost every proposition that emanated from the latter was pooh-poohed or so little heeded that it has been a question whether the British representatives should not withdraw from the Conference. Some concession has, however, been made as to the futility of quarantines, whether on sea or on land. But what astounded the members present was the affirmation made by an English physician to the effect that cholera was not imported from India, but that each epidemic that has occurred in Europe originated from local causes. There is, however, nothing new in this theory, for it will be remembered that M. Jules Guérin has entertained it, though almost alone, for nearly half a century.

OLD SHOES AND CHOLERA.

A propos of cholera, the report of the Society of Hygiene of Milan draws attention to the influence of old shoes as a means of propagating the disease. When a person treads a soil more or less damp in a locality infected, there is every chance of his conveying the germs in the manner described.

PLANTS IN BEDROOMS.

It is generally supposed that the presence of plants in a bedroom is prejudicial to the health of its occupants. This, it appears, is an error, for at a recent meeting of the Congress of Pharmaciens one of the members stated that plants, far from being hurtful, on the contrary, in disengaging ozone from the vapour emanating from them, render the atmosphere of a room in a state of humidity perfectly healthy; moreover, it is averred that ozone, in destroying the microbes, and thus purifying the air, is favourable to persons affected with pulmonary consumption. Hence the Congress recommended that, while bedrooms may be furnished with plants which disengage the most ozone, flowers should be eliminated from them, as they do not possess the same virtues as the plants.

THE QUEEN'S BIRTHDAY.

Every year on the occasion of the Queen's birthday a grand dinner is given at the British Embassy. That for this year took place on Saturday last, when the principal members of the British Colony were present, the medical profession being represented by the Hon. Dr. Alan Herbert, Dr. Boggs, Dr. Loughman, Dr. Douglas Hogg, and Dr. Faure-Miller. Lord Lyons received his guests with his usual affability. His dinners are excellent, and his wines are reputed to be of the choicest kind and quality, yet his lordship never partakes of the latter. He is most abstemious, and appears to enjoy the best of health.

THE ILLNESS OF M. ANATOLE DE LA FORGE.

M. Anatole de la Forge, Vice-President of the Chamber of Deputies, who was one of those who were struck with insolation at the funeral of Victor Hugo, and was rather seriously affected, is now, I am glad to say, out of all danger. M. Anatole de la Forge is one of those rare Frenchmen who are teetotallers. He told me that he has never taken a glass of wine since he was a boy, drinks nothing but water, and has always enjoyed very good health. He is now sixty-five years of age.

At its last meeting, the Paris Faculty of Medicine decided that the prize founded by M. Lacaze, of the value of 11,400 francs, and which is given every two years, will next be awarded in 1886 to the author of the best work on Phthisis and Typhoid Fever.

Paris, June 9th.

EGYPT.

(*From a Correspondent.*)

The examinations at the medical school mentioned in my last letter were concluded on May 23rd. The whole number of students was 147, consisting of 126 students of medicine, 4 of pharmacy, and 17 of midwifery. Of the medical students, 84 passed and 41 were referred to their previous studies for a year, while one was ill during the examinations. There were 20 students of the fifth and final year, of whom 16 passed, and these 16 will now undergo a competitive examination to elect 5 of their number as house-surgeons at £72 a year, while the remaining 11 will become unpaid dressers, and work in the native hospital. In twelve months' time the whole 16 will be again examined in order to receive their certificates to practise. The whole of the 4 apothecaries and 17 pupil midwives were passed by the examiners. Each class was examined by its own native professor, aided by an independent examiner, of whom there were the following eleven:—Dr. Abbate Pasha (President), Dr. Grant Bey, Dr. Murison, Dr. Milton, Dr. Sandwith, Dr. Hess, Dr. Engel, Messrs. Hooker and Sickenberger for pharmacy, and two natives. This is the first year that students have been subjected to the test of written papers and clinical examination in addition to the stereotyped *vivâ voce* of a quarter of an hour, during which the candidate repeats from memory in the exact words of the text-book all that he knows of the disease in question. Thus it happens that a subject approached from an unaccustomed point of view, a cross-examination on his own glib quotations, or a question requiring reasoning intelligence on the part of the candidate, usually baffles him effectually. This is even more noticeable among the girl students than the boys. It is wonderful, however, how much young men may learn who study anatomy without dissecting, and even without seeing other preparations than those of wax, who are taught organic without the rudiments of inorganic chemistry, who do no practical ward work, and who are entirely dependent on professors, some of whom have little or no interest in, or aptitude for, the lessons they deliver. No great hope can be entertained of this school of medicine until the scholars are taught a European tongue, but the slight reforms which have taken place during the last twelve months are sufficient to encourage those in Cairo who are unselfishly striving for the school's welfare.

Cairo, May, 1885.

MEDICAL NOTES IN PARLIAMENT.

Inoculation against Cholera.

In the House of Commons, on the 8th inst., Dr. Cameron asked the President of the Local Government Board whether his attention had been called to the report of a Committee of the Academy of Medicine and Surgery of Barcelona appointed to investigate Dr. Ferrán's system of protected inoculation against cholera; whether he had observed that, according to Spanish telegrams published in the newspapers, the Spanish Government on May 28th appointed a commission to proceed to the cholera-stricken district of Valencia along with Dr. Ferrán, with the view of testing his system; and whether, in view of the probable fleeting nature of the opportunity now presented for an investigation, and the trifling expense required for the despatch of a small commission to an accessible country like Spain, he would consider the propriety of at once nominating such a commission without awaiting the result of protracted negotiations with the Indian Government as to their bearing a portion of the cost.—Mr. Russell replied that attention had been called to the report referred to, but that the Local Government Board did not deem it necessary at the present time to despatch a commission on behalf of the Board with the view of investigating Dr. Ferrán's system of inoculation.

ROYAL COLLEGE OF PHYSICIANS.

At an extraordinary Comitia held on Thursday last, a communication was received from the secretaries of the British Association for the Advancement of Science in reference to the establishment of an International Scientific Association, and, in proposing that a preliminary scientific conference be held in London in 1888, asking for the cooperation of the College in promoting that object. It was felt, however, that the matter would be better left in the hands of the British Association.

The report of the Committee on the Lunacy Bill was received and adopted; as was also the report from the Croonian Trust Committee.

ROYAL COLLEGE OF SURGEONS.

At an ordinary meeting of the Council of the Roya College of Surgeons of England held on Thursday last, unanimous resolution of condolence with Miss Arnott on th death of Mr. Moncrieff Arnott was passed. The nominatio of Hunterian Professors was proceeded with, Messrs. Treve Stewart, Brailey, and Alexander Hill being appointed. Th nomination of Professors of Surgery was postponed. Dr Wooldridge, of Guy's Hospital, was appointed Arris and Gale lecturer for the ensuing year. Mr. Bland Sutton, of the Middlesex Hospital, was appointed Erasmus Wilson lecturer

A letter from Mrs. Cæsar Hawkins was read, offering a marble bust of her late husband, to be placed in the College The bust was accepted, and the best thanks of the Counci were voted.

It was proposed that the College take 100 copies of the autotype reproduction of the original manuscripts of lectures given by Harvey in and after the year 1616, and which have recently been discovered in the British Museum after having been lost for above 100 years. This proposition was agreed to.

A communication was received from Dr. Hickman, forwarding a memorial signed by more than 600 teachers, practitioners, and students of medicine, urging that the Royal College of Physicians of London and the Royal College of Surgeons of England be amalgamated, forming a Royal College of Medicine; and that this College of Medicine be empowered to grant the degree or title of Doctor of Medicine, giving the power to practise in medicine, surgery, and midwifery. The memorial was referred to the joint committee on the title of Doctor.

Thanks were voted to Mr. Marshall for the report of the General Medical Council which was received from him.

A letter was received from Dr. Hack Tuke, calling attention to the in many respects objectionable clauses 12 and 13 of the Lunacy Act Amendment Bill now before the House of Lords, and suggesting that a protest should proceed from the Council.

On the 8th of May, 1884, a resolution was adopted by the Council, that a meeting of the Fellows and Members be called every year, to which a report from the Council be presented; it was now resolved that a meeting be held in October, of which due notice shall be given, and at which the report of the Council be presented. A letter from the Association of Members, containing resolutions passed at their last meeting, was presented.

A communication from the secretaries of the British

Association for the Advancement of Science was received, asking the opinion of the Council as to the advisability of holding a Preliminary Scientific Congress in London in 1888, and also whether the Council would give facilities for the holding of meetings. The Council replied that it was not called upon to give an opinion as to the advisability of holding such congress considering its present information, but would be prepared to offer what facilities it could for promoting its success.

Obituary.

SIR WILLIAM MURE MUIR, M.D., K.C.B.

SIR WILLIAM MUIR, the late Director-General of the Army Medical Department, died on the 2nd inst., after a long illness. In the autumn of 1877 he first exhibited symptoms of the disease which ultimately killed him. At that time his life was in jeopardy from the effects of very severe intestinal hæmorrhage and hæmatemesis. He rallied, returned to his duty, and discharged it manfully to the end of his Director-Generalship in May, 1882. But the manifestations of abdominal disease in 1877 were but the indications of the beginning of the end, and Sir William Muir's most attached friends could not have wished to have seen his life prolonged after so lingering and protracted an illness. He had suffered at different times during his tropical service from the effects of climatic disease.

Sir William Mure Muir, K.C.B., late Director-General, Army Medical Department, received his professional education at the University of Edinburgh and at St. George's Hospital, London. He obtained the degree of M.D. Edinburgh University, and the diploma of the College of Surgeons, Edinburgh, in 1840.

Dr. Muir entered the service as an assistant surgeon on Nov. 22nd, 1842, and finally became Director-General in April, 1874. He served upon full pay for nearly forty years, of which twenty-four were passed upon foreign service, in the Mediterranean, Turkey, and Crimea, Mauritius, Bombay, Madras, China, North America, and Bengal. He landed with his regiment, the 33rd, at Old Fort, and continued in charge of it throughout the siege of Sebastopol, having been present at the Alma, Inkerman, sortie of Oct. 26th, and at the attacks on the Redan, and siege and fall of Sebastopol (medal and three clasps, Knight of the Legion of Honour and Turkish medal). In February, 1885, and again in September, he was specially recommended by Mr. Alexander, the principal medical officer of the Light Division, for promotion on account of the zealous and careful manner in which he performed his duty, both in Bulgaria during the ravages of cholera, and in the Crimea. With the exception of a few days' sickness on his first landing at Eupatoria, he never quitted his post. He was also recommended for advancement by Generals Simpson and Codrington. Dr. Muir subsequently proceeded with his regiment to Mauritius, and thence to Bombay, and served in the Indian Mutiny in 1857-58. He was selected as principal medical officer of the Expeditionary Force to China under Sir Hope Grant in 1860, and was mentioned in despatches (medal with two clasps and C.B.); and for the able manner in which he had conducted the medical duties of the Expedition he was specially promoted to the rank of Inspector-General.

In 1861 Dr. Muir was nominated to accompany the Expedition to North America in the *Trent* affair, and marched with the troops through Nova Scotia. He remained in North America upwards of five years. During the active operations of 1862-63 in the United States he paid several visits, as an amateur, to the army of the Potomac, and on May 14th, 1865, he proceeded, at the request of the British Government, to Washington, in view of reporting on the sanitary and field medical arrangements of the army. He visited all the principal hospitals, and the hospitals of the Confederate Army at Richmond, &c., and embodied the results in a very valuable report. He had the highest opinion of the American nation, of their energy, force of character, and fertility of resource, and always looked back upon his experience and upon the friendships he contracted in that country with the liveliest satisfaction.

In 1868 he became principal medical officer of Her Majesty's British troops in Bengal, where he remained for upwards of four years, and was then selected as head of the Sanitary Branch of the Army Medical Department, London.

On the retirement of Sir Galbraith Logan, Sir William Muir was promoted to the post of Director-General for a term of seven years, from April 1st, 1874, which period was specially extended to May 6th, 1882.

On Dr. Muir's relinquishing his post in India for that of head of the sanitary branch of the War Office in this country, the Government of India expressed in very warm terms their appreciation of his services, and of the important assistance the Government had derived from his experience, advice, and practical suggestions. Lord Napier of Magdala also recorded his opinion of the very valuable character of Dr. Muir's services, and of the independence, honesty, and sound judgment he had always exhibited.

In 1868 Dr. Muir became honorary physician to the Queen, and in 1873 he was made a K.C.B., and awarded a good service pension in 1880.

There are two ways of speaking of the dead. One is the principle of "De mortuis nil nisi bonum;" the other and truer

> "Speak of me as I am; nothing extenuate,
> Nor set down aught in malice."

Sir William Muir would himself have shrunk from all exaggerated estimates of his ability and services. What was he, then? What did he seem to be to those who knew him well and who were honoured with his confidence and friendship? He was one of Nature's noblemen: he had an eminently handsome head, finely chiselled features expressive of intelligence and strength; he was large of heart and intellect, and there was nothing mean about him; he had great courage, independence of character, and directness of aim: he was not, like Admirable Byng, for example, a man of personal courage, but, where responsibility was concerned, calling for a council of war. With Sir William Muir the boldest was often the best policy, because it was the boldest. Once having pictured to himself the object to be attained, he never faltered. Through good report or evil report (and it was for years the latter) it was all the same; he could labour and wait, for he had that strength which comes partly of moral robustness of character, partly of intellectual conviction—qualities which characterised statesmen of a past age. United with this power, this self-reliance, there were great gentleness and naturalness, and these formed that personal charm which first attracted and then welded his friends to him. Of course he made enemies: no man of character and independence can do otherwise; but those who knew him best believed in him most. He did what he thought right, and no doubt estranged some of his friends by doing it; but he gave the public medical service the power of growth and development by an unflinching persistence in his policy. Most, if not all, have come to recognise that the usefulness of the Department has enormously increased with its increase of power. The indebtedness of the medical service to Sir William Muir is undoubted, and at his last public appearance at a departmental dinner he was evidently overcome by emotion at the ovation he received. No one could have held a more enviable position as a regimental officer than did the late Director-General in the earlier stages of his career. When he left the 42nd Highlanders, the commanding officer told him, to prevent disappointment, that he could not expect in another corps to have the same amount of influence; but in the 33rd Regiment he gradually won the respect and esteem of all, and his influence for good was universally acknowledged. Still, he always recognised that responsibility and power must go hand-in-hand, and he regarded the position of the medical service under the regimental system as inherently defective. What is best for the public service as a whole, he was never tired of proclaiming, is best for the medical service, and the only tenable ground for it to occupy. In everything appertaining to the sick and wounded soldier, to the hospital service and its administration, and to army hygiene, the medical officer should be supreme; and within the limits which were clearly defined and circumscribed by his sphere of duty, the medical officer should be endowed with authority in the interest of the soldier and the State. His experience had taught him that of all men the medical officer had the greatest sympathy with the private soldier; and that, next to the general in command, the principal medical officer of a force in the field had the greatest responsibility, but lacked the power to get his requirements fulfilled. What had been begun by his predecessors in the direction of the department was consolidated and completed under his *régime*. He gave the medical service an autonomy. The Warrant of 1879, under the terms of which all army medical officers are serving at the present time, was unquestionably an enormous stride in advance of anything that had gone before it. If Sir William Muir erred, it was in favour of military efficiency, and in view of securing military success. Impressed with what he had seen of war on a vast scale in America and elsewhere, he had learnt the paramount importance of disencumbering a marching and fighting force of its sick and wounded and all unnecessary impedimenta, so as to leave the general free to make a rapid movement and inflict a prompt and decisive blow whenever and wherever this could be effected. By an irony of fate not at all uncommon in the world, the system was condemned by those in whose interest it was mainly designed. Still, he was right. When war comes upon this nation in earnest, and upon a scale compared with which our small campaigns will sink into insignificance, it will be seen that the provisions for such a war cannot keep pace with the requirements of a luxurious and selfish age.

Sir William Muir never lost sight of the true dignity of his calling; and, like all high-minded men, regarded the artificial glare reflected from military rank, dress, or titular distinction as nothing compared with the true light reflected from the scientific attainments of the members of a benevolent and dignified profession. Whatever may be the hankering of some after these things, progress and respect can only come from advancing knowledge and usefulness. All the public medical services have a common cause and a common calling, and are but a part of the great medical profession, the members of which have only to be true to themselves. Time will do the rest. What the late Sir William Muir accomplished will be regarded more and more highly as time goes on, because his work will go on developing, and the wounded in the field, the sick in our war hospitals, and those who have charge of them, will reap the benefit of his labours even after his name is forgotten.

JAMES MONCRIEFF ARNOTT, F.R.C.S., F.R.S.

Mr. James Moncrieff Arnott, whose death recently occurred at his residence in Sussex-gardens, Hyde-park, was born at Chapel, Fifeshire, in 1794. He was educated at the High School and University of Edinburgh, in this latter institution commencing those professional studies which he subsequently continued in London, Vienna, and Paris. Mr. Arnott was one of the founders of the medical school of the Middlesex Hospital fifty years ago, along with Sir Charles Bell, Dr. Copland, Dr. Leighton, Dr. (afterwards Sir Thomas) Watson, and others, and for many years acted as surgeon to the Middlesex Hospital and North London Hospital. He was afterwards successively selected to occupy the chairs of Surgery in King's College and University College. In 1840 Mr. Arnott was nominated one of the Council of the Royal College of Surgeons; he was elected a Fellow in 1843, and later on became a member of the Court of Examiners of that body, of which he had twice been elected to the presidency. In 1860 he was elected representative of the College in the General Council of Medical Education and Registration of the United Kingdom. Mr. Arnott held the appointment of surgeon in ordinary to the late Prince Consort. The subject of our notice was in every sense of the word a truly great man, conscious of his abilities to assume the highest responsibilities of his profession, and most conscientiously discharging those duties when undertaken. He belonged to the epoch of British surgery when the old traditions were being sent to the winds, and is best remembered in actual surgical work as having successfully performed a then difficult plastic operation for ruptured perineum. His writings consisted chiefly of contributions to the Transactions of the Royal Medical and Chirurgical Society.

JOSEPH BUNNY, M.D.

By the death, on the 30th ult., of Dr. Joseph Bunny, Newbury has lost one of its oldest and most respected inhabitants. He received his medical education at Edinburgh, Guy's, and St. Thomas's, and in 1823 obtained the degree of M.D. at the University of Edinburgh, having previously, in 1820, become a Member of the Royal College of Surgeons of England, and a Licentiate of the Society of Apothecaries. He commenced the practice of his profession in Newbury, and in 1839 was elected borough coroner, an office which he held until 1873, when he resigned. Dr. Bunny was a Fellow of the Obstetrical and Medical Societies of London, a magistrate for the borough, and held several other offices connected with local charities. He was the first hon. surgeon to the Newbury Dispensary, established in 1835, and performed the duties for ten years, after which he was hon. consulting surgeon until the year 1877. For some years past his health had been such as to gradually induce him to seek release from his practice and to take a less active part in public matters. The deceased had attained the age of eighty-six years.

Medical News.

Royal College of Surgeons of England.—The following Members, having passed the Final Examination for the Fellowship on May 28th, 29th, and 30th, and June 1st, were at a meeting of the Council on the 11th inst. admitted Fellows of the College:—

Barlow, John, Elmbank-crescent, Glasgow; Diploma of Membership dated Nov, 17th. 1874.
Penny, William J., Caledonia-place, Clifton, Bristol; Nov. 19th, 1879.
Galpin, George Luck, Great Marlborough-street; Nov. 18th, 1880.
Pedley, Frederick Newland, Finsbury-square; April 21st, 1881.
Bass, Frederick, Union-road, Jan. 18th, 1882.
Collier, Joseph, Manchester; July 17th, 1882.
Thring, Edward Thomas, Torrington-square; July 20th, 1882.
Voss, Francis Henry Vivian, Clapton-square; July 31st, 1882.
Worthington, Sidney, Pattensweir, Enfield; Nov. 16th, 1882.
Saneyoshi, Yashuzumi, St. Thomas's Hospital; Jan. 24th, 1883.
Pigeon, Henry Walter, Royal Infirmary, Manchester; Jan. 25th, 1883.
Wynter, Walter Essex, Templecombe, Twickenham; Jan. 26th, 1883.
Vogan, James Norman, Hatchlands, Redhill; April 18th, 1883.
Paget, Stephen, Grosvenor-street; July 23rd, 1883.
Steedman, J. Francis, High Ercall Hall, Wellington; Nov. 13th, 1883.
Muspratt, Charles Drummond, Nightingale-lane; July 30th, 1884.

Three other candidates passed the examination, but two not having attained the legal age (twenty-five), and one not possessing a medical qualification, will receive their diplomas at future meetings of the Council when qualified. Seven candidates failed to reach the required standard, and were referred to their professional studies for one year.

Mr. Edward Albert Schäfer, M.R.C.S., F.R.S., will commence a course of three lectures on "Secretion" on Monday, the 15th inst., at 4 o'clock.

Society of Apothecaries.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on the *4th inst.*:—

Shaw, Wm. Wright, M.R.C.S., St. Bartholomew's Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination:—

William Gilmore Ellis and Percy John Rendall, St. Bartholomew's Hospital; John Elliotson Pennington Sparrow, King's College.

The Hull General Infirmary has received a bequest of £10,000.

The second annual dinner of the Association of Public Sanitary Inspectors was held on the 6th inst.

Dr. Lewis A. Stimson has been elected Professor of Anatomy in the University of the city of New York, to succeed the late Professor Darling.

The epidemic of small-pox at Burslem is reported to be spreading; nearly forty persons are suffering from the disease, and several deaths have occurred.

According to the *Calcutta Englishman*, Dr. Fraser has been shot in Borneo during an attack made by natives upon the expedition of which he was a member.

Superannuation Allowance.—Mr. G. Macdonogh, late medical officer for the Clapham district, has received a superannuation allowance of £80 a year.

At the College of Surgeons on Tuesday evening last, a private conversazione was given by the President, Mr. Cooper Forster. About 1200 guests were present.

Vaccination Officers Association.—At the next meeting of members of this Association, to be held on June 20th, at 2.30 P.M., at the Charing-cross Hospital Medical School, Chandos-street, Dr. Robert Cory will read a paper on "Some Medical Facts relating to Vaccination, of which it is desirable Vaccination Officers should have more extended Knowledge." Remarks will also be made on "Duties devolving on Vaccination Officers during Epidemics of Small-pox."

ROYAL SOCIETY.—Sir Andrew Clark, M.D., Henry Hicks, M.D., Arthur Milnes Marshall, M.D., and Professor Sydney Ringer have been elected Fellows of the Royal Society.

SIR WATKIN WILLIAMS WYNN, Bart., M.P., has expressed his intention of erecting a cottage hospital at Ruabon, North Wales, to the memory of his uncle, the late baronet.

THE French Association for the Advancement of the Sciences will hold its fourteenth session at Grenoble from the 13th to the 20th of August, under the presidency of M. Verneuil.

ST. ANDREWS GRADUATES' ASSOCIATION. — The members of this Association will hold a conversazione on Wednesday evening next at the rooms in Chandos-street, Cavendish-square.

MIDDLESEX HOSPITAL STUDENTS' SOCIETY. — The members of this Society will hold a conversazione on the 25th inst., when Dr. B. W. Richardson, F.R.S., has consented to deliver an address on "Medical Poets."

THE VOLUNTEER MEDICAL STAFF CORPS.—By the permission of the Lord Mayor, a meeting will take place at the Mansion House on June 19th, at 3 P.M., with the object of furthering the interests of the Volunteer Medical Staff Corps.

HYDROPHOBIA.—On the 8th inst. two cases of hydrophobia were reported in Manchester, a man and woman having died of the disease at the infirmary. On the 7th inst. in Dublin twenty-one persons were bitten by two rabid dogs.

HANDEL BICENTENARY FESTIVAL.—This festival will be held at the Crystal Palace on the 19th, 22nd, 24th, and 26th inst. The rehearsal takes place on the first day, a performance of "The Messiah" on the second, selections on the third, and "Israel in Egypt" on the fourth.

UNIVERSITY OF OXFORD.—At a congregation held on the 4th inst. the degree of M.D. was conferred on E. Daly (University) and E. Jenkins (Trinity). Convocation has passed a decree conferring the degree of M.A. upon Arthur Thompson, M.R.C.S., Lecturer in Human Anatomy in the University Museum.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination held on June 4th and 5th, twenty-five candidates presented themselves, nine as local surveyors and sixteen as inspectors. Certificates of competency were awarded to three candidates of the former class and to fourteen of the latter.

THE thirtieth annual festival of the Poplar Hospital for Accidents was held on the 10th inst., when it was stated that the number of in-patients admitted to the hospital during the past year was 612, the number of out-patients treated being 7289. During the evening subscriptions amounting to £1450 were announced.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—A meeting of this Society was held on Tuesday last at the rooms of the Medical Society, the President, Dr. Norman Kerr, in the chair. A paper was read by Dr. J. Muir Howie (Liverpool) on "The Treatment of Inebriety." The physical aspect of the disease in dipsomania was specially treated of. A discussion followed, in which Sir Edwin Saunders, Dr. Bridgwater, Dr. Longhurst, Mr. F. J. Gray, and Mr. H. R. Kerr took part.

AT the St. Pancras Coroner's Court on the 8th inst., inquests were held on the bodies of four persons, and at the close of the inquiries the foreman of the jury entered a protest on behalf of himself and fellow-jurors against the disgraceful mortuary accommodation, or rather want of accommodation, in St. Pancras. A rider was appended to each of the verdicts, declaring that the present dangerous and unhealthy state of the mortuary, and the want of proper accommodation for the holding of inquests, showed that the St. Pancras Vestry had no consideration for the living and a total disregard of the dead.

THE ROYAL ACADEMY OF MEDICINE OF BELGIUM.—The following subjects have been selected for theses, and to the writer of the most meritorious essay on each a prize will be presented by this institution:—1. The determination by experiments and applications the degree to which spectral analysis may be realised in the researches of forensic medicine and the medical police. 2. The experimental determination of the influence which desiccation exerts when employed as a means of conserving the simple vegetable medicaments. 3. The physiological effect of sanguineous depletion, either local or general; its indications and contraindications in the treatment of disease. 4. Description and critical review of the different methods of surgical dressing and of the antiseptic treatment of wounds and surgical affections. 5. The study of erysipelas, *charbonneux* or *rouget*, of swine, as relating to its causes, manifestations, lesions, prophylaxis, and treatment, and to establishing eventually its relations with carbuncular or bacterian diseases.

CITY-ROAD CHEST HOSPITAL.—On the 5th inst. a meeting was held at the Mansion House in aid of the fund for completing the new wing now being added to this institution. Last year as many as 7439 patients were admitted, and the numbers are constantly increasing. The special feature of the hospital is that beds are kept for the reception of persons presenting themselves for relief as out-patients who are suffering from acute and dangerous diseases of the chest of recent origin, and who cannot be properly treated unless immediately received as in-patients. The total income last year was £4424. For completing the extension the sum of £5000 is still needed.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The following office-bearers have been elected for the ensuing year:—Committee: the Presidents of the Colleges of Physicians and Surgeons, E. Adrien, L. Atthill, J. T. Banks, J. Hawtrey Benson, E. Bennett, D. Brady, E. Brunker, Henry G. Croly, B. G. Darley, J. Denham, G. F. Duffey, J. F. Duncan, T. Fitzpatrick, S. Gordon, T. Grimshaw, J. Harvey, A. H. Jacob, H. Kennedy, G. H. Kidd, J. Little, J. M'Donnell, R. M'Donnell, W. J. Martin, E. D. Mapother, A. H. Marks, William Moore, G. Morrogh, J. F. Pollock, Sir G. H. Porter, P. C. Smyly, W. Stokes, R. Tagert, J. Tufnell, J. H. Wharton. Trustees: J. F. Duncan, John M'Donnell, J. H. Wharton. Hon. Treasurer: W. Thomson. Hon. Secretaries: J. M. Finny and J. W. Moore. Hon. Secretary for India and the Colonies: Henry King. Acting Secretary: A. H. Benson.

THE LOWER THAMES VALLEY MAIN SEWERAGE BILL. By the new Bill, which dissolves the Lower Thames Valley Main Sewerage Board and constitutes a new united district for the disposal of the sewage of the Lower Thames Valley Main Sewerage District, it is proposed that the district of the Joint Board shall be subdivided, so that Richmond and the parishes constituting the Richmond Rural Sanitary Authority (Richmond Union, Barnes, Kew, Mortlake, and Petersham) shall be combined as one district; that Kingston-Surbiton District and the district of New Malden shall be constituted as another authority under the name of the Kingston District; and that the Local Government Districts of East Molesey, Hampton Wick, Ham-common, and Teddington, and the Kingston Union, shall be formed into a third district. Power is given to each of the newly constituted authorities to make due provision for the disposal of the sewage of its district, failure to make such provision within two years from the passing of the Act to render the authority liable to be declared in default.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BANHAM, HENRY FRENCH, M.A., M.D.Cantab., L.S.A.Lond., has been appointed Senior Physician to the Royal Berkshire Hospital, vice Wells, deceased.

BLUMER, F. MILNES, B.A.Dunelm., M.B., C.M.Ed., has been appointed House-Surgeon to the Staffordshire General Infirmary, vice William Edward Rawson, M.R.C.S., resigned.

BURRIDGE, JOHN WALTER, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Eastham District of the Wirral Union, vice Wykes.

CANNY, DENIS JOSEPH, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the District [illegible] th Wales.

CH[illegible] M.D., C.M.Ed., M.R.C.S., has been appointed [illegible] for the Woolton District of the Prescot Union, vice Wood.

COLLINS, JOHN SHRILL, M.D.Q.U.I., M.R.C.S., has been appointed Assistant House-Surgeon to the Hull Royal Infirmary, vice H. C. Chambers, L.R.C.P., M.R.C.S., resigned.

Davis, Henry, M.R.C.S., L.S.A.Lond., has been appointed Second Chloroformist to the Middlesex Hospital.

Embrey, Mr. George, has been appointed Public Analyst for the County of Gloucester.

Harrison, J. W., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Sandwich and Ash Districts, vice Horne.

Houseman, James Gilpin, M.B., has been appointed Honorary Physician to the Newcastle-on-Tyne Sick Children's Hospital, vice David Drummond, M.D., resigned.

Jack, Robert Nilson, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Health Officer for Stawell, Victoria.

Kerr, Elias Wm., M.B., M.Ch.T.C.D., has been appointed Medical Officer for the Eastern District and the Workhouse of the Cerne Union, vice McEnery.

Lacey, Thomas Samuel, L.R.C.S.I. & L.M., L.R.C.P.Ed., has been appointed Medical Officer for the Royton and Thornham District of the Oldham Union.

Macdonald, Hugh, M.D., M.Ch.Glas., has been appointed Government Health Officer and Surgeon to the Gaol, Lyttleton, New Zealand.

Morrison, W., M.A., M.D. & C.M.Glas., has been appointed Resident Surgeon to Ballarat District Hospital, Victoria, Australia.

Smith, Henry Strode, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Eighth District of the Axbridge Union, vice Tarleton.

Watson, Thomas Alfred, M.B., C.M.Ed., has been appointed Assistant House-Surgeon to the South Dispensary, Liverpool.

Births, Marriages, and Deaths.

BIRTHS.

Barber.—On the 4th inst., at Clapham, S.W., the wife of H. Vaughan Barber, M.A., L.R.C.P.Lond., of Stuart-road, High Wycombe, of a daughter.

Bott.—On the 3rd inst., at Brentford, the wife of Henry Bott, L.R.C.P., of a son.

Brown.—On the 1st inst., at Ainslie-place, Edinburgh, the wife of J. Graham Brown, M.D., F.R.C.P.E., of a son.

Cane.—On the 3rd inst., at The Mansion House, Peterborough, the wife of Leonard Cane, M.D., B.S., of a son.

Chipperfield.—On the 6th inst., at Bloxham, Oxon., the wife of T. J. B. Pearse Chipperfield, L.R.C.P., M.R.C.S. (prematurely), of twin sons.

Creed.—On the 31st ult., at Rathkeale House, Girdler's-road, West Kensington-park, the wife of Charles Philip Creed, M.R.C.S., L.R.C.P.Ed., of a son.

Douglas.—On the 30th ult., at New-walk, Leicester, the wife of Claude Douglas, M.R.C.S., *of a daughter.*

Fraser.—On the 4th inst., at Western Lodge, Romford, Essex, the wife of James Alexander Fraser, M.R.C.S., L.R.C.P., of a daughter.

Lord.—On the 1st inst., at Wilton House, Landport-terrace, Southsea, the wife of Frederick Lord, L.R.C.P., L.R.C.S.Ed., of a daughter.

Ross.—On the 3rd inst., at Macquarie-street, Sydney, New South Wales, the wife of E. Fairfax Ross, M.D., of a son.

Sankey.—On the 1st inst., at Boreatton-park, Salop, the wife of Arthur O. Sankey, of a son.

MARRIAGES.

Down—Jones.—On the 4th inst., at St. John's, Chelsea, Hubert Vincent, second son of George Down, M.D., of Holmhurst, St. John's-hill, S.W., late of South Kensington and Montague-place, W.C., to Margaret, only daughter of the late Benjamin Jones, Esq., of Britannia-road, Fulham.

Evans—Wright.—On the 3rd inst., at S. Mary's, Lower Merton, Surrey, by the Rev. J. C. Erck, Frederick William, M.D., M.R.C.S., &c., eldest surviving son of the late Alderman Thomas Evans, of Cardiff, Surgeon, to Henrietta Clarissa, youngest daughter of the late Richard Wright, Esq.

***Phillips—Goetz.**—On the 3rd inst., at All Saints', Margaret-street,* John Phillips, B.A., M.D. (Cantab.), M.R.C.P., of Harley-street, eldest son of the late L. Phillips, of Birchmoor, near Bedford, to Jessie, eldest daughter of the late E. L. Goetz, of Gloucester-gardens, Hyde-park.

Stables—Drury.—On the 2nd inst., at Rathgar, Dublin, Walter Williams Godfrey Stables, M.R.C.S., of Heckington, Lincolnshire, eldest son of the late Walter Williams Stables, of Crosland Hall, Huddersfield, Jun., Esq., to Isabella Mary, youngest daughter of the late Thomas Drury, of Dartry, Upper Rathmines, County Dublin, J.P.

Walker—Lester.—On the 9th inst., at St. Matthias, Earl's-court, S.W., by the Rev. Henry Westall, of St. Cuthbert's, South Kensington, Charles Edward Walker, M.B., M.R.C.S., of Hurworth-on-Tees, Darlington, second son of W. H. Walker, M.D., Aldbro', Darlington, to Annette Curtis, youngest daughter of the late Rev. J. W. Lester, D.D., Vicar of Lower Norwood, Surrey. No cards.

DEATHS.

Fisher.—On the 7th inst., suddenly, at Haselly Manor, near Warwick, Thomas Fisher, M.D., of Stone House, near Wigan, aged 81.

Ling.—On the 1st inst., at The Beeches, Saxmundham, Suffolk, John Mitford Ling, M.R.C.S., L.S.A.Lond., aged 75.

Livingston.—On the 10th inst., suddenly, at his residence, High Barnet, John Livingston, M.D., aged 45.

Stuart.—On the 1st ult., at Fraserburg, Cape of Good Hope, of typhoid fever, Donald Stuart, M.B., C.M.Aberd., late of Kenmay, Aberdeenshire, N.B., aged 31 years and 11 months. Deeply regretted.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 15.

Royal London Ophthalmic Hospital, Moorfields.—Operations, *10.30 a.m., and each day at the same hour.*

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 p.m., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 p.m., and on Tuesdays at the same hour.

Hospital for Women, Soho-square.—Operations, 2 p.m., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Royal College of Surgeons of England.—4 p.m. Mr. A. E. Schafer: *Secretion.*

Tuesday, June 16.

Guy's Hospital.—Operations, 1.30 p.m., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 p.m.

St. Thomas's Hospital.—Ophthalmic Operations, 4 p.m.; Friday, 2 p.m.

Cancer Hospital, Brompton.—Operations, 2.30 p.m.; Saturday, 2.30 p.m.

Westminster Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 2.30 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Wednesday, June 17.

National Orthopædic Hospital.—Operations, 10 a.m.

Middlesex Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital.—Operations, 1.30 p.m., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 p.m.

St. Mary's Hospital.—Operations, 1.30 p.m. Skin Department: 9.30 a.m., on Tuesdays and Fridays.

St. Thomas's Hospital.—Operations, 1.30 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m., and on Thursday and Saturday at the same hour.

Great Northern Central Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 p.m.

University College Hospital.—Operations, 2 p.m.; Saturday, 2 p.m. Skin Department: 1.45 p.m.; Saturday, 9.15 a.m.

Royal Free Hospital.—Operations, 2 p.m.

King's College Hospital.—Operations, 3 to 4 p.m.

Royal College of Surgeons of England.—4 p.m. Mr. A. E. Schafer: Secretion.

Royal Meteorological Society.—7 p.m. Dr. William Marcet: Meteorological Observations made on a Trip up the Nile, February and March, 1885.—Dr. H. H. Hildebrandsson: The Mean Direction of Cirrus Clouds over Europe.—Dr. A. Woeikoff: On the Influence of Accumulations of Snow on Climate.—Mr. Charles Harding: Note on the Weather of January, 1881.—Lieut. Alexander Leeper: Results of Meteorological Observations made in the Solomon Group, 1882-84.—Mr. David Cunningham: Graphic Hygrometrical Table.

Thursday, June 18.

St. George's Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital.—Surgical Consultations, 1.30 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

North-West London Hospital.—Operations, 2.30 p.m.

Friday, June 19.

St. George's Hospital.—Ophthalmic Operations, 1.30 p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

King's College Hospital.—Operations, 2 p.m.

Royal College of Surgeons of England.—4 p.m. Mr. A. E. Schafer: Secretion.

Saturday, June 20.

King's College Hospital.—Operations, 1 p.m.

Royal Free Hospital.—Operations, 2 p.m.

Middlesex Hospital.—Operations, 2 p.m.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A DUTCH ACCOUNT OF HOTTENTOT PATHOLOGY.

A Dutch practitioner who has lived for twenty years in South Africa sends to an Amsterdam medical journal some particulars of native customs and beliefs. The uterus is supposed to have a great tendency after parturition to fly upwards, and consequently after the second stage of labour the funis is carefully tied to one of the woman's great toes, so as to prevent the placenta from slipping away, and as soon as the third stage is completed she is tightly bound with a cloth or a cord at the level of the umbilicus, for if not the restless uterus would ascend into the breast. After the birth of a stillborn child nothing can prevent the womb from betaking itself into different regions and then performing unpleasant and painful gyrations. The writer mentions an old native woman who came to him with a scirrhus of the mamma. She complained of occasional pain in the abdomen, but was not seriously concerned about it, for, said she, "I know what that is; it is the womb going round; have I not had a stillborn child? From that time there can be no rest for the womb; he [the womb] keeps springing round and round, not always, but at times, perhaps for three months, and then for a fortnight he is still. Sometimes he sits here [indicating the spleen]; sometimes here [touching the right breast]; sometimes he sits behind my shoulder-bone, and then he burns like a coal of fire." The uterus has to answer in the native mind for most of the ills to which female flesh is heir; has she a colic, sickness, or any abdominal trouble, it is always the old story—"the womb is going round." When listening to a gesticulating patient describing her malady and enunciating her diagnosis of the case, it is frequently somewhat difficult for a medical man to keep his countenance. It is utterly useless for him to attempt to reason with the woman or explain to her the absurdity of the position she has taken up. She will only doubt his skill, and scornfully reply: "Doctor must not say it is not so, for I know that it is." Amongst the natives the new-born babe is treated to a purifying draught of the father's freshly passed urine. The whites, some of whom are nearly as ignorant and superstitious as the natives, employ a quack "wonder-doctor" as a substitute.

Surgeon, V.A.—1. The regulations for the reserve forces provide for only two grades of medical officers of volunteers—acting surgeon and surgeon. If our correspondent has completed twelve years' service as surgeon, he might apply to the Secretary of State for War, through his commanding officer, for promotion to the rank of surgeon-major, as is granted to militia surgeons.—2. The relative rank of acting surgeon of volunteers is lieutenant, and that of surgeon is captain.

F. C. P.—He is referred to a general notice at the head of this column.

CARE OF EPILEPTICS.

To the Editor of THE LANCET.

SIR,—The parents of a lad subject to epileptic fits followed by uncontrollable outbursts of temper are most anxious to get him admitted into a home where he will be well cared for and medically treated, as he is getting beyond their control. Some of your numerous correspondents would confer a favour by affording such information as will [illegible].

I am, Sir, yours faithfully,

M. G. E.

[illegible]

DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—May I ask through the medium of your columns for particulars [illegible] treatment for diphtheria. Perhaps [illegible] will be able to suggest a line of treatment more [illegible] results than any known to

Yours truly,

L.S.A.

MEDICAL MISSION WORK IN CHINA.

FROM the report for 1884 of the Hang Chow Medical Mission in connexion with the Church Missionary Society, it appears that the total number of out-patients attended during the year was 2929, and of in-patients 203, patients visited at their homes bringing up the total of those who were relieved by the mission to 4707. Anæmia, as in the case of the Chin-Chew Hospital, the work of which was noticed in a recent issue, formed a large percentage of the cases coming under treatment. It is especially common amongst women, and is easily accounted for by the following causes: marrying too young, hæmorrhagic losses during confinement, suckling their children for three and four years, and their cramped feet, which prevent them taking proper and sufficient exercise. Diseases of the skin and digestive system and malarious fever also each contribute a large percentage of patients. A new hospital, comprising a refuge for opium smokers, which was its *raison d'être* when commenced some thirteen months ago, and a medical school are almost completed, and will, it is expected, be opened in a few months.

Dr. Whitelegge.—The statement is corrected in another column.

Mr. S. Johns.—The Preliminary is indispensable.

Mr. G. E. Walker.—Next week.

THE RISK OF SMALL-POX.

To the Editor of THE LANCET.

SIR,—The following two cases of small-pox have been selected from nearly fifty which occurred during an epidemic about thirty-five years ago in a parish in Essex comprising a population of about 1500.

Two cases presented themselves simultaneously in opposite parts of the parish. Having obtained authority from the Board of Guardians for a general revaccination, I lost as little time as possible in commencing my defensive operations. I began, of course, with the families connected with the patients; but, as in those days no lymph-bearing calves were in existence, and the Privy Council had not come forward as protectionists, some considerable time elapsed before obtaining a sufficient supply of lymph, which was then supplied either on points or glasses. That delay gave the enemy a considerable advantage, hence the large number of cases. In the course of about two months I had operated on more than 1000 persons, not a single one of whom was subsequently attacked by the disease, although I had no means whatever for isolation.

1. Thomas H—— occupied a cottage which formed part of a "row" in which occurred a case of confluent small-pox of a malignant character. I at once vaccinated and revaccinated every person in the row except T. H——, who could be neither persuaded nor compelled to submit to the operation, in which he "had no faith." I did, however, insist upon vaccinating every other member of the family, which was a large one. His neighbour died, and he, by way of daring, assisted at the funeral. Within ten days he required the like service from others, and he was the only one in the row attacked.

2. John H—— lived in a hamlet in which several cases occurred, about two miles from my residence. I at once put them under a state of siege by vaccinating every person except J. H——, whose avocation as an ash-gatherer took him much from home. I met him, however, several times, and he always declared his intention of "coming to be cut." Unfortunately for him and myself, he never did come. He, too, had a very severe attack. Early in the morning of the third day, whilst his wife was dozing after her night's vigil, he escaped in his nightshirt and ran to the village, two miles distant. The ground was covered with snow. When summoned I found him crouching in the corner of a coal-hole which he had been in the habit of emptying, shaking with cold and fear, and declaring that the bleeding was caused by people shooting at him. I procured for him some hot brandy-and-water, whilst a tumbril was being prepared with straw and blankets, in which I sent him home, having first provided a strait jacket, which I had shown a man in attendance how to apply when the patient had been placed in bed. Late that evening I was again summoned to the hamlet, as the patient had "broken loose." On my arrival I found two men holding him down. Discovering that the jacket had not been properly applied, I reversed it, and, having secured him to the bedstead, left him in the charge of the two men. After a month or so he was convalescent, and is now alive. His face is deeply pitted, but in no other respect is he the worse.

Now, when it is considered that all the above number of cases had been nursed by the wives or mothers, who had uninterrupted intercourse with their respective families; that they occupied cottages with no more than two bedrooms; and that after the first three weeks of the outbreak in no single instance did more than one case exist in a house—when all these circumstances are considered, I do affirm that should any person still doubt that vaccination is a sure and certain protection against small-pox, such person is entitled to no sympathy should he ever suffer the penalty which his blindness or obstinacy is sooner or later likely to inflict upon him.—Your obedient servant,

London, May 12th, 1885. WILLIAM B. OWEN.

A PLAGUE OF FLIES.

To the Editor of THE LANCET.

SIR,—Can any of your readers suggest the best method of ridding a house of flies? At the house I live in they are a regular pest, swarming in thousands.

I am, Sir, yours faithfully,

June 11th, 1885. VEXATUS.

SMOKING IN ASTHMA.

IN Henry Taylor's autobiography (Longmans, 1885, vol. ii., p. 153) occurs the following passage:—"The spasmodic form of disease has never returned. The cigarette which brought it to such a sudden end was made of a mild tobacco in paper slightly impregnated with saltpetre; not so manufactured with any medicinal view, but merely to make it burn better. It happened to be at hand when I was advised to try smoking tobacco; and it was this particular combination which saved me, for neither saltpetre nor tobacco pure and simple, or in other proportions, was of much use."

Mr. J. C. Richardson.—There can be no doubt that a medical man called to assist a midwife is entitled to a fee independent of the midwife's fee.

DOES COCAINE AFFECT DEEP-SEATED PARTS?

To the Editor of THE LANCET.

SIR,—In reply to Mr. Jackman's queries in your last issue I think that if a solution of cocaine of sufficient strength be applied for a long enough time, it will be found that the sensibility of the iris is reduced to zero. As I pointed out in a former communication, when solutions of atropine, eserine, or cocaine are applied to the surface of the conjunctiva, they percolate through the cornea, and come into actual contact with the iris, and the extent of their influence upon that membrane depends upon the strength of the solution, the frequency of the instillation, and the time that has been allowed to elapse from the date of the first application; thus the aqueous humour of a cocainised eye will produce anæsthesia of its fellow if applied to it. In one case in which I tried this experiment I was surprised to find the pupil contract under the influence of aqueous humour, which, so far as I knew, contained only a mydriatic—a circumstance that was explained by the fact, subsequently ascertained, that the patient had been using a solution of eserine prescribed elsewhere. There is undoubtedly a considerable difference in patients; in fact, I had one who behaved exactly in the manner described by your correspondent; but my experience after forty-one extractions for cataract under cocaine, and numerous other operations, is that the effect, on the whole, even so far as the iris is concerned, is very satisfactory. I questioned a patient on this point on whom I performed iridectomy. I said, "Did you feel any pain?" His reply was, "Well, not to say pain." "Did you feel anything?" "Well, I felt you were doing something, but the eye was numb." In very nervous patients it is well to apply the solution after section of the cornea, and to wait a few minutes before excising the iris; this brings the anæsthetic as thoroughly into contact with the iris as with the cornea, and there can be no doubt as to the result; or the iris may be excised with the knife in passing it across the chamber, a method I frequently practised before the introduction of cocaine when operating for cataract, as I constantly did without any general anæsthetic. I did not, however, find it necessary to do this, or to apply the cocaine after incising the cornea, when I operated upon Mr. Copeland. The solution employed in that case was one of 6 per cent., instilled every five minutes for half an hour.

I am, Sir, your obedient servant,

CHARLES BELL TAYLOR, M.D., F.R.C.S.,
Surgeon to the Nottingham and Midland Eye Infirmary.

June 8th, 1885.

R. D. H.—There would seem to be no course open to our correspondent but to put pressure on the Local Government Board.

Mr. H. W. Freeman's paper is marked for insertion.

Mr. L. Wies.—We do not prescribe.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

The Cavendish Lecture

ON

HYSTERIA AND ITS COUNTERFEIT PRESENTMENTS.

Delivered before the West London Medico-Chirurgical Society, on Friday, June 5th, 1885,

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.

(Concluded from p. 1072.)

I PASS on to another group of cases. Hettie R——, a girl, fourteen years of age, came under my care about three years ago. Shortly before that she lost her father, and her brother died in a fit. These losses affected her deeply, and she was attacked with violent spasmodic jerkings of the muscles of the right arm and leg, and of the same side of the body, and with right hemianæsthesia. She remained in the hospital for some few weeks, and left it well, having been cured (it was thought) by the daily application of the faradic current along the spine. She continued well until four-and-twenty hours before her admission for the second time into St. Thomas's Hospital on April 14th of this year. She was now seventeen. She went out to service a week previously; found the work hard and her mistress exacting; and was attacked with a kind of fit, followed by similar jerking movements to those which she had suffered from on the first occasion. She was a healthy-looking, well-conducted, sensible girl. She had violent rhythmical spasmodic movements of the arms and legs, neck and trunk. These were most marked on the right side, and did not involve the muscles of expression or the tongue. They ceased during sleep. She had anæsthesia on the right side of the body, with impairment of smell and taste, and colour-blindness in the corresponding eye. There was slight tenderness in the ovarian regions, but chiefly in the right. Within a day or two the movements on the left side of the body subsided; but those on the right were more persistent, and though they practically ceased after a few days under the renewed use of faradaism (which she begged might be employed), there were slight and trivial recurrences from time to time. Her sensory phenomena varied. At the end of a few days the right-sided anæsthesia became replaced by hyperæsthesia; a little later the anæsthesia appeared on the left side of the body; then she presented universal analgesia, and shortly afterwards the analgesia was limited to the lower extremities. It may be noticed, that during all the variations of distribution of disturbances of ordinary sensation, colour-blindness persisted in the right eye and involved that eye alone; and that during at any rate part of the time in which she was suffering from general analgesia there was general loss of feeling in the lips, gums, tongue, and inside of the mouth, with notable impairment of taste and smell. During her stay in the hospital she had several fits, lasting from a few minutes to half an hour. These began with general tremors, passing into convulsive movements of a violent kind (associated with general rigidity), and were attended during the latter part of their duration by voluble, somewhat incoherent talk, which related largely to recent events and to [illegible] she had seen, and in which she made statements as to [illegible] which she would certainly not have made in her [illegible]. She appeared therefore to be conscious, but she had no recollection whatever after the fits of anything that had occurred during their continuance. It may be added that the fits were sometimes preceded by globus and followed by headache, and were unattended with [illegible] or discharge of evacuations. But lividity of [illegible] was observed once or twice at the early period of an [illegible] in one (during which the temperature was taken) [illegible] 101°. In the rigidity above referred to the [illegible] arched, the arms extended horizontally, and [illegible] extremities straight, the feet being extended at [illegible], and the toes flexed. The teeth were [illegible]. The right leg remained rigid for some hours after [illegible]. In this leg also at this time were observed [illegible] tendon reflexes and ankle-clonus. The last remaining hysterical phenomena were colour-blindness and a hitch in the action of the right leg in walking. She is now well.

There can be no doubt that this girl has been suffering from hysteria. The emotional origin of the attacks, the shifting sensory disturbances, the rhythmical muscular contractions, the fits, the ovarian tenderness, collectively establish the truth of this diagnosis. But it is worth while to observe that there was nothing in the manner or conduct or mental state of the girl to suggest hysteria. She was bright and sensible; she had a healthy appreciation of the ludicrous, and could join in the laugh which some of her performances excited, and especially was most anxious to be cured. Indeed, as has already been stated, it was at her own request that faradaism was applied; because, although the pain was dreaded by her, she had a vivid belief that she had been cured by it before. It is interesting to note that one of her fits came on at night, during sleep.

My special object in quoting this case is to call attention to the mental condition of hysterical patients in connexion with the convulsive attacks to which they are liable. It had generally been taught that hysterical fits were fundamentally different from epileptic fits, and that there could seldom or never be any real difficulty for a well-informed medical man to distinguish the one form of seizure from the other. It has latterly, however, been admitted that in certain aggravated forms of hysteria fits occur which partake of the special features of the paroxysmal attacks of both affections; and the term "hystero-epilepsy" has been invented to meet the requirements of the case. The classical descriptions of epileptic fits and of hysterical fits are founded on fact; their accuracy is confirmed every day; and it will be admitted that a typical epileptic fit and a typical hysterical fit stand in essential and striking contrast with one another. But it is rather by their collective phenomena than by any one distinctive feature that they must be discriminated. Even the sudden attack of profound unconsciousness which so commonly and characteristically marks the onset of the epileptic seizure, and has been largely regarded as the test and proof of epilepsy, may be present, I think, in affections which have no true claim to be regarded as epileptic; and may certainly be absent from fits whose epileptic nature is unquestionable. Another remarkable feature of epilepsy is the tendency which many epileptics have (sometimes previous to a convulsive seizure, sometimes in place of a fit, but more commonly in immediate succession to a fit, or rather perhaps as the later stage of it) to pass into a dreamy condition of shorter or longer duration; in which the mind is possessed, in one case, by wild frenzy, in another case by apparently a calculating and calm resolve to carry out some atrocious design; in which, in another case, the patient simply acts absurdly or incongruously, or even comports himself much as he would do in health; in which the motor functions obey the mental impulses as in the normal state; but on recovery from which the patient has either no recollection whatever of what happened during his period of mental aberration, or merely that kind of recollection which one has of a dream.

About two years ago a servant girl, seventeen years of age, came under my care. For two years she had suffered from headaches. At first they came on at long intervals, and lasted continuously for a week or two at a time. Latterly they had become more frequent and more severe, and attended with drowsiness, which made it difficult for her to perform her ordinary duties. On Easter Monday one of her attacks came on, and it continued until the following Friday, on the afternoon of which day she left her mistress's house to visit her mother, who lived four miles and a half away. She had often traversed the road before, and knew it perfectly; but, suffering still from headache, she got confused, and lost her way. She did not reach her destination till 10 o'clock P.M. on Saturday night, when she recollects sitting down upon her mother's doorstep, where she became unconscious, and remained so until aroused by some neighbour who recognised her. She retained a vague recollection of wandering about these many hours, and of occasionally asking her way of passers-by. What was her condition during all this time? Was she in an epileptic trance, or was her condition a phase of hysteria? There was no history of her ever having had a fit of any kind. She was healthy-looking and free from paralysis. But she was peculiarly slow in her speech and movements. She had spots of hyperæsthesia just above both clavicles and under both mammæ; and the right ovarian region was tender. Moreover, she had marked analgesia of both arms. During her stay in the hospital she suffered much from headache, but improved in this and other respects; the analgesia left the right arm; and the left became both analgesic and anæsthetic. There was still anæsthesia of the forearms when she left the hospital. I may add that careful inquiries were made, and left no doubt that the story the girl gave of herself was true. Collateral facts prove, I think, that the girl was hysterical, and render it pretty certain that her temporary mental confusion or obliviousness was also hysterical. But what she did is not unlike what epileptics do; of which I will quote a recent example.

A young man, a jeweller, twenty-two years old, had had fits for two years past. The first occurred just after getting out of the train on arriving at London Bridge. He came to himself nine hours and a half later, when he found himself in a cab near his own home in the suburbs of London. On getting out of the cab he was going to pay the driver, but was told that payment had already been made; and he found later that the fare had been taken out of his own purse. Another fit occurred a month ago. He was in Berwick-street, felt giddy, ran on a little way, and fell. He recollects nothing more until he found himself walking somewhere near the Great Northern Railway Station, a part of London in which he had no business. The last fit occurred near the Blind Asylum at St. George's-circus. He cannot recall the beginning of the fit, and recollects nothing until he awoke to consciousness some hours later, and found himself still walking somewhere about the circus. Now here, no doubt, the condition was epileptic, and the loss of consciousness, or rather the forgetfulness of what occurred to him during the attack, was complete. There is no evidence as to what he did during the periods which were a blank to him; though on one occasion it seems pretty clear that he must have appeared so far helpess as to justify his being taken care of. But on two other occasions at least, and in one of them for a period of some hours, his behaviour must have been such as not to attract any special attention. He probably acted like the girl, and as one knows epileptics are liable to act.

In the case of Hettie R——, the periods of mental aberration which followed her fits, in which she appeared to be conscious of what was going on around her, and talked incoherently, were a blank when she came to herself. She declared, and I believe, that she had no recollection whatever of anything that happened during their continuance. One of the most remarkable examples of this kind of phenomenon in an hysterical case that I know of was published by me in the *British Medical Journal* six years ago. The case is a voluminous one, and, indeed, is still in progress; but I will quote briefly so much of it as relates to the subject I am considering. The patient was a young lady whose hysterical symptoms commenced in the year 1873. They presented many variations during the next few years. She had cataleptic attacks, in which she became plastic, and in which her arms and legs could be bent into various attitudes, wherein they would remain indefinitely; and she had violent convulsions, alternating with a strange mental condition, which, after a few months, became established, and then continued for two years without change. During this period she could move her limbs freely, and, indeed, seemed to have much muscular power, yet was unable to rise from her bed, or even to feed herself without assistance. The least exertion was usually followed by an attack of profound syncope. She could feel, but there was total insensibility to pain, and she was absolutely deaf. On the other hand, she was closely observant of all that was going on round her; was voluble in her talk, her vocabulary being peculiar; would often sing; would never take food from anyone of her immediate friends or relatives; and was vindictive, biting if she had the opportunity, and concealing sticks or knives under her pillow, and striking anyone with them if she had the chance. For a long time her doctor was the only person she cared to see, or would obey; as soon as she caught sight of him, she would tremble with pleasure and eagerness, hold out her arms to him, catch hold of his hand, and fondle it in hers, and begin to talk volubly. She would first say, "Paws," which meant "shake hands"; and if he failed to respond she would become sullen, cry, and refuse food until he did; then she would say she had a lot to tell him, and would recount all that had occurred since his last visit. His visits, which were for the purpose of feeding her, were made three or four times a day. During the whole of this time she had a strong antipathy to her father and mother and other relatives, and did not even seem to recognise them for whom they were. She knew them, however, from one another, and gave them names. One sister she called "Dog," another sister "Fox," her mother was "that one," and her aunt was "the other one." I do not think that her father had a name, but she disliked him more than all the rest; and for a long time, as her fits were disappearing (for she remained liable to them), his presence alone caused them. At the end of the two years her mother, one morning, heard her heave a deep sigh, and saw her head drop suddenly on one side on the pillow. She thought she was dying, rushed up to her, and said, in alarm, "Do you know me, Edith?" when the daughter replied "Yes," in a scarcely audible whisper. This was the first indication of hearing and of recognising her mother which she had manifested. She remained in this condition for a few minutes, and then suddenly passed again into her maniacal state. From this time forward she had nearly every day one of these lucid intervals. At first they lasted perhaps for about ten minutes, but gradually they increased in duration, so that at the end of six months they often persisted from half an hour to two hours. They always came on in the manner above described, and ended suddenly. They were always characterised by the same phenomena; and these, it will be observed, were in many respects the exact converse of those which marked her maniacal state. While in them she seemed to possess all her normal qualities of mind; was quiet, lady-like, and affectionate; and knew and appreciated her father, mother, and other relatives and friends. But there was utter bodily prostration; she spoke in a whisper; her eyelids were closed without the power of opening, and tremulous, though she could see when they were raised for her; and her hearing, which in her other state was absolutely lost, was now preternaturally acute. Indeed, any slight shock, and especially a sudden noise, would render her at once maniacal. On the first occasion on which her doctor saw her in a lucid interval, he conversed with her quietly; asked her to put out her tongue, which she did; and then invited her to take food as usual, which she declined, but in a quiet, lady-like way, and simply because she was not hungry. He asked her if she knew him, and she said she did not. He then tried to feed her with a spoon, when she suddenly opened her eyes, was excited as usual at his presence, and at once greeted him with "Paws, doctor." The lucid intervals gradually increased in duration, and at the end of another five or six months they occasionally lasted for days together; and, moreover, as they increased in length the other intervals diminished, until after a while they constituted what might be termed mad fits of a few minutes' duration only. Further, the extreme bodily prostration of her lucid periods gradually lessened; and by degrees the power of opening her eyes, of speaking aloud, and of taking food, without going off into a maniacal paroxysm, was restored. In 1877 she had recovered completely.

During the prevalence of the alternating conditions above described she appeared while in the one to know absolutely nothing of what had occurred in the other, but retained a vivid recollection of all that had happened to her in the previous period of the same condition. Her recovery was of very short duration; and for a long time past she has been suffering from extreme contracture of one of her lower extremities, associated with occasional cataleptic attacks, lasting for several weeks at a time.

It seems to me that this girl's maniacal condition (of which she retained no recollection whatever when she was in her normal mental state) was the same in quality as the condition presented by Hettie R—— after the convulsive attacks; and I repeat that I can see no real difference between their mental affection and that which is presented by many epileptics.

In reference to the relation of hysteria to epilepsy, I may just allude, in passing, to the case of a young girl, Rose D——, who was three or four times under my care during the years 1881, 1882, and 1883. Her fits began when she was fourteen, a year before I first saw her. She was a plump, healthy-looking girl, suffering from fits which came on irregularly, having sometimes as many as fifteen in the day. They were generally preceded by a cry, sometimes by more than one; were attended with loss of consciousness and convulsions; and lasted, perhaps, for about half a minute. They were certainly, I think, epileptic. In favour of which view, it may be stated, that they came on when she was asleep, as well as when she was awake; that they were generally preceded by an aura beginning in the right thigh, rising to the right side of the chest, and then involving the right arm from the fingers upwards; that she once bit her tongue in a severe fit; and that she often passed urine during an attack. But she emerged from her fits into consciousness generally with a smile on her face, and occasionally laughing. Latterly she once or twice came to herself crying. It is further stated in the notes of the case, that when she was last under treatment she more than once was laughing during an entire fit, and on one or two occasions was attacked with causeless and uncontrollable laughter, without loss of consciousness.

3. I had intended, when first the subject matter of this lecture began to take form in my mind, to devote no inconsiderable proportion of it to the discussion of hysterical anæsthesia and its relations with anæsthesia arising under other conditions. This subject, however, is too extensive to be treated of at the fag-end of a lecture. And so I will pass on to the consideration of some of the visceral phenomena of hysteria.

a. In the *Practitioner* of 1883 I published some remarks on "The Functional Vomiting of Hysteria." This, as we all know, is a very common affection, and often a very serious one; and generally, I have no reason to doubt, depends on irritability of the stomach itself. But occasionally it is due to other causes, as one of the cases I there related proves.

A delicate-looking girl of fourteen came under my care in 1881, suffering from an hysterical affection of the right hip. This she had been troubled with for two years; and, though she had never had hysterical fits, or had hysterical symptoms in the popular sense of the term, every surgeon who had seen her previously, and my surgical colleagues at St. Thomas's now, had no doubt of the hysterical, or at any rate functional, nature of her disease. She improved slightly under treatment, during a three months' residence in the hospital. She was readmitted five months later, still complaining in some degree of her hip, but suffering mainly from constant vomiting, which she had had for several months, and great consequent emaciation and debility. She weighed only 3 st. 3½ lb., and was bedridden. Her cheeks were flushed, and her face wore a mixed expression of apathy and martyr-like resignation. She had no pain except in her hip; she vomited after every meal; and her abdomen was shrunken and concave. From the time of her admission she continued to vomit after whatever was taken, the vomit consisting mainly of the food swallowed and mucus, and the sickness generally coming on a few minutes after ingestion. It was sometimes, however, delayed for ten minutes or a quarter of an hour. Various measures were adopted to relieve the suspected irritability of the stomach; and at length she was fed only with enemata. During this time she lost weight slightly, her temperature sank to 96°, and her pulse varied from 42 to 60. After the feeding with enemata had been persisted in for ten days, the administration of milk by the mouth in teaspoonful doses was commenced, at first only three or four times a day, and then every hour. But again we were disappointed, for after every dose the milk was speedily vomited; in fact, her stomach appeared to be just as irritable now as it had been at first. At the end of four or five days, being much puzzled and disheartened, I gave more serious thought to the incidents of the case than I had previously done. I now called to mind that she had never complained of actual pain or tenderness in the region of the stomach; that she was not flatulent; that her vomiting was an easy process with her; and especially that she brought back the greater part of the minutest quantities of food taken, and in whatever form it was given. And I asked myself the question, Was it possible that the bulk of her food never entered the stomach at all, but was retained in the œsophagus, and thence regurgitated? I now made the girl drink a dessertspoonful of milk in my presence, and watched the progress of events. She swallowed it without difficulty, and evidently it went beyond the influence of the pharynx; then she appeared to suffer from some discomfort, and in the course of a minute or so (without any very violent effort, but with a certain amount of spasmodic action) the milk was gulped up into her mouth. I brought the resident assistant-surgeon to see the case with me; and at my request, and in my presence, he passed a medium-sized indiarubber tube along the œsophagus into the stomach, and then injected into that organ about three ounces of milk. There was a little impediment to the passage of the instrument through the lower part of the canal, but it was readily overcome, and was evidently not due to any organic disease. The milk thus injected did not provoke any feeling of sickness, and remained in the stomach without causing discomfort. She did, immediately after the removal of the tube, regurgitate a small quantity of milk, but this was clearly only the milk which had escaped into the œsophagus during the withdrawal of the instrument. It was intended to feed her daily by the tube, but she never required it again during her further stay of six weeks in the hospital. The result showed that my suspicions were correct; and it is an interesting practical fact that the spasmodic action of the œsophagus, which had persisted for months, was cured by a single operation.

In the same paper I quoted the case of a man who was affected with what seems to have been the same kind of œsophageal affection as that which this girl presented, but who manifested no other hysterical symptoms, and whose temporary spasm of the œsophagus can scarcely have been hysterical. The patient was over fifty years of age, and had suddenly (a week before I saw him) become incapable of swallowing. He had been a healthy man, and there was no explanation of his state that I could make out; he had been wholly without food for a week, and had consequently lost flesh and strength. On making him take food in my presence I found that he masticated properly, and that the act of deglutition was performed without difficulty, but that what he swallowed was immediately ejected with violence. The impediment was clearly in the upper part of the œsophagus. Having failed to detect any lesion by external examination or by looking down the throat, I proceeded to pass a bougie. There was a very slight impediment at the upper part of the gullet, which was readily overcome, and the instrument was pushed on into the stomach. The effect was marvellous; the patient swallowed without the slightest difficulty immediately afterwards, and swallowed thenceforth as readily as he had always done up to the time of his illness. He came under my care again six months later for a temporary attack of catarrhal jaundice, from which he recovered in the course of a week or ten days. He had had no recurrence of dysphagia.

On the same occasion I published a third case, which was one of painful interest to me, for I failed to recognise its nature, and it is mainly, perhaps solely, to this failure that the patient's death must be attributed. The patient was a young man, whose illness had commenced six months before I took charge of him, and was attributed by him to his having drunk a pot of beer which irritated his gullet as it passed down. From that time he seems to have had constant sickness after food, and to have vomited from five minutes to half an hour after every meal. He was very thin and weak when I first saw him, but I was unable to detect any evidence of abdominal disease. I attached very little importance to the attributed origin of his illness, and assumed that as his vomiting was often, indeed generally, delayed for some considerable time after the ingestion of food, it was due either to pyloric obstruction or to some functional disturbance of the stomach referable to disease external to it. In other words, though I never ventured to commit myself as to the exact nature of his malady, I believed that he had organic disease, either chronic ulcer or cancer of the stomach, or disseminated peritoneal cancer, or tubercle. There were obvious and strong reasons against each of these views of his case; but, believing as I did that the vomited matters came from the stomach, I never thought of passing a bougie or of feeding him by the œsophagus tube. His vomiting persisted up to the time of his death. At the autopsy his stomach and other abdominal organs were all found to be healthy, and the only lesion discovered was dilatation of the œsophagus with hypertrophy of its walls. Whether this condition was really a consequence of irritation caused by the draught of beer to which the patient referred his illness, or whether it was analogous to the similar condition observed in the large intestine in cases of neglected peritoneal constipation—a condition secondary either to sluggish action of the dilated tube, or to spasmodic action of the part below,—I cannot venture to say. But if the latter view be correct, the essential similarity of this case to the other two becomes apparent.

b. Besides aphonia, other symptoms referable to the respiratory organs occur in cases of hysteria. I shall not enumerate them, but will briefly speak of two or three. I recollect some five-and-twenty years or more ago a nurse, aged thirty-six, was admitted into the hospital under the care of one of my senior colleagues. She was suffering, not only from aphonia, but from difficulty of breathing. Her medical attendant believed the case to be one of hysteria, but he was not absolutely sure upon that point; and, as her dyspnœa increased in urgency, he judged it advisable to have tracheotomy performed. The operation was done by a surgeon (long since dead), who transfixed the trachea and *passed the trocar and cannula into the apex of the right* pleura. Strange to say, the patient seemed to be immediately benefited; but within half an hour the right pleura had become distended with air, and difficulty of breathing of another kind had come on. She died in a couple of days from the results of the operation; and the larynx was found to be absolutely healthy. The case occurred before the invention of the laryngoscope, or the thermometer had come into use as an agent in diagnosis. Here the dyspnœa was probably due to functional affection of the larynx. In a case of my own, that of a highly hysterical girl of eighteen (who was under treatment for many months with hysterical paraplegia, attacks of hystero-epilepsy, and analgesia), dyspnœa of an asthmatic character formed one of her symptoms. This came on quite suddenly on the first occasion, and was unattended with rise of temperature; but it continued for five or six weeks with varying severity, and during this period became associated with rapid breathing, frequent cough, and scanty expectoration, occasionally tinged with blood. At times, too, there was a slight rise of temperature. An attack a few months later presented similar phenomena. But rapidity of breathing may constitute the sole respiratory trouble. I recollect about ten years ago having a female patient under my care—I think between thirty and forty years of age—who, with other hysterical symptoms, suffered from attacks of rapid breathing, during which, sometimes only for a few minutes, sometimes for several hours, her respirations would rise to 70 or 80 in the minute, her pulse remaining normal in frequency, and there being no other indication whatever of intrathoracic disease. In 1883 Dr. Mackey of Birmingham published in THE LANCET a similar case in which the respiratory acts varied between 88 and 128 in the minute, while the pulse ranged from 59 to 72, and the temperature was normal.

c. Circulatory troubles are also common in hysteria. Limited pulsations, mainly of the abdominal aorta, simulating aneurysm, have often been referred to this affection. Rapid action of the heart, tumultuous and irregular action, and extreme feebleness of action, are severally frequent consequences of emotional conditons, and necessarily, therefore, are frequently observed in hysterical patients. I have recently seen a remarkable case of what seems to me to have been functional, not improbably hysterical, rapid action of the heart. A lady, thirty years of age, three years married and without children, had a slight attack of pneumonia, from which, at the end of about five weeks, she had recovered sufficiently to be allowed to go out for a drive. This seems to have upset her, for shortly afterwards she was attacked with retching, difficulty of breathing, and nervousness. The retching subsided in the course of a day or two, but it was noticed that her pulse was remarkably rapid. It reached 180 in the minute, and as her aspect became rather livid, and she was unable to lie down, her medical attendant naturally became uneasy. When I saw her a week later she was sitting up in bed; she was spare, pale, and delicate-looking, with a shade of anxiety on her countenance, but nevertheless she was bright and cheerful, conversed pleasantly and without difficulty, and certainly did not look seriously ill. Her breath was a little quickened, but her heart was beating at the rate of 192 in the minute; the action was regular, the pulse was feeble, and the cardiac sounds, which were sharp and short, were free from murmur. The lungs were both healthy, and there was no evidence of disease in any other organ of the body. Her tongue was a little coated, and her appetite bad. This rapid action of the heart, which had existed for a week when I saw her, continued for another week, when it fell almost suddenly to 110, and then to 92. I visited her again soon afterwards, when she seemed quite well, but her pulse was still 92. The patient had always been delicate and nervous, but had never presented definite hysterical symptoms; formerly she had been stout, but some years ago became slim, and has since continued so. She never had rheumatism or any other serious disease; but during the last few years she has had several attacks like the present, and there is reason to believe that her pulse has been generally rapid. There was no protrusion of the eyeballs or enlargement of the thyroid. So far as I can call to mind, I have only on two other occasions met in adults with more rapid action of the heart than was presented by this lady. But the patients here referred to were dangerously ill, and their extreme rapidity of pulse occurred at times when death seemed imminent. One case was that of a young woman, in whom in the course of a very severe relapse of enteric fever, and when for some days her death was expected momentarily, the pulse continued at the rate of 198 in the minute. She ultimately recovered. The other case was that of a middle-aged man who had been suffering for two years from gradually increasing pallor and debility, and whom, when he came under my care, I thought to be suffering from progressive anæmia. He improved, however, considerably under treatment, and left the hospital stronger and better than he had been for many months. One day, shortly after his admission, he fell, without obvious cause, into a state of collapse, and occasionally this was so extreme that his recovery was despaired of. During these attacks his pulse from time to time ran up to 200. His collapse was not due to hæmorrhage.

4. At the beginning of my lecture, gentlemen, I said I should not then attempt to define hysteria, or to fix the landmarks which separate it from other functional nervous disorders. At the close of my lecture, guided in part by the cases that have been passed in review, I return to the subject I at first dismissed. I have quoted a series of cases which I have labelled "hysteria," and have compared them with other cases, some of which I have regarded as not hysterical. But what right have I to make this distinction between them? Again, I ask what is hysteria?

Typical hysteria occurs, or generally appears for the first time, in persons who from sex, age, or the conditions in which they live, are specially emotional; it is attended with marked emotional disturbance, sometimes with intellectual disturbance, and is characterised by a liability to convulsive attacks, and to various affections of the sensory and motor systems, which are sometimes of general distribution, sometimes hemiplegic, sometimes paraplegic, sometimes limited to particular nerves or groups of nerves. The affection, moreover, is various in its incidence, and liable to sudden onset, sudden change, sudden recovery—circumstances which prove its independence of organic nervous disease.

But hysteria may occur with many of its characteristic symptoms highly aggravated, with many of its characteristic symptoms in complete abeyance, or indicated haply by only one or two trivial incidents. The emotional and intellectual disturbance may pass into genuine madness, as in so-called "hysterical mania." The convulsive attacks may resemble, if they do not merge in, those of epilepsy, as in cases of so-called "hystero-epilepsy." On the other hand, there may not be, and there may never have been, definite or discoverable emotional disturbance or tendency, never any convulsive attacks, never hemiplegia or paraplegia, and, indeed, the manifestations of the disease may be limited, so far as I know, to an attack of neuralgia, to painfulness and tenderness of a particular organ, to paralysis or spasm of a single muscle or a group of muscles, or to some functional disorder of a single viscus.

In other words, so-called "hysteria" may, as it seems to me, consist in excess, diminution, or modification of all or any of the nervous functions, whether of the brain, the ganglia at the base of the brain, the medulla, the cord, the sensory or motor nerves, or the sympathetic system. And hence, by specially implicating particular parts, it may, in its symptoms, resemble, more or less accurately, a large number of organic diseases of the nervous system developed in the same parts. And hence also, and on similar grounds, it may resemble, more or less accurately, many other recognised functional disorders of the nervous system, which are regarded as definite diseases, and have received distinctive names, if indeed, under such circumstances, it does not become indentical with them.

No doubt an emotional element preponderates in cases generally regarded as hysterical; and, for the most part, definite hysterical symptoms are the consequence either of overwhelming emotions excited in healthy minds, or of lesser emotional influences acting on minds already in a state of unstable equilibrium. But it must not be forgotten that emotional disturbance characterises, or complicates, a large number of intra-cranial disorders which are not of hysterical origin. It is of the very essence of insanity; in chorea, in megrim, and in epilepsy, especially in the first, the emotions are generally implicated; the presence of syphilitic tumours, and generally disease in the neighbourhood of the fourth ventricle, evoke a tendency to laugh and cry, and to become erotic; and the lowness of spirits and proneness to tears which follow hæmorrhage into the brain are well known. Emotional affection is, therefore, no monopoly of hysteria. And not only so; for while we might naturally expect emotional symptoms to preponderate when the other hysterial symptoms are such as depend on cerebral disturbance, we might as naturally expect these to be less and less pronounced in proportion as the hysterial phenomena become more and more limited to remote and less important parts of the nervous organism. And so no doubt it often is.

The view which I am inclined to hold with respect to hysteria and other functional nervous diseases, and to their mutual relationships, is as follows. There are many functional diseases of the nervous system, among which may be included insanity in many of its forms, epilepsy in its different varieties, chorea, megrim, neuralgia, and hysteria. These are all characterised by groups of symptoms referable to excitement, depression or aberration of the nervous functions, and mainly of those of the nervous centres. They are severally distinguished clinically by the association of definite groups of symptoms; determined either by the particular part of the nervous system affected, by the special kind of affection which takes place therein, or by the order and mutual relation of events. And we regard them as specific diseases, because experience teaches us that such groups of symptoms are so commonly observed under particular conditions as to show that specific causes must underlie them and determine their concurrence. But the causes of the different affections are for the most part closely related to one another, if not identical; the individual symptoms which, by their modes of aggregation, constitute the several diseases as we know them are common more or less to all of them; many cases occur in which it is difficult, if not impossible, to determine satisfactorily in which category they should be placed; and, indeed, as it seems to me, there is no substantial line of demarcation between the diseases.

If this view be correct, the terms insanity, epilepsy, hysteria, &c., would still imply well-marked, and for the most part permanent, varieties of functional nervous diseases; but the recognition of intermediate types, or the failure to form a definite diagnosis in every case, could not be taken to imply ignorance; and it would follow that many of the limited functional disturbances of which several of my cases furnish examples have little or no claim to be called hysterical (an adjective which is usually, and perhaps conveniently, applied to them), unless the meaning of the word hysteria be so far extended as to include all functional affections for which no other name has yet been invented.

In conclusion, I may venture to say, the more extensive my experience of nervous diseases has become, the more I have learnt to recognise the following facts: that many grave nervous disorders which, from their mode of onset, their symptoms, and their progress, would seem to imply the presence of organic disease, present post mortem no visible pathological change, that many such disorders, progressive and threatening a fatal issue, ultimately recover perfectly, that limited or localised nervous phenomena, paralytic or spasmodic, anæsthetic or neuralgic, come and go without obvious cause; and the more I have been brought to believe that functional nervous disorders capable of cure simulate the most serious as well as the most trivial cases of organic nervous disease. It may be admitted that emotional persons, and persons of marked hysterical tendencies, are more than others liable to suffer from the affections here referred to; but some of the most remarkable examples I have met with have been in patients who, apart from their particular malady, have presented no sign or symptom whatever of the hysterical condition.

I thank you, Mr. President and Gentlemen, for the high honour you have done me in inviting me to deliver this address, and for the kind patience with which you have listened to it. I wish it had been more worthy of the occasion and of my audience.

St. Mary's Hospital.—The festival dinner in aid of the funds of this hospital is to be held on Wednesday next, at the Langham Hotel. George Palmer, Esq., M.P., will preside.

ON

HEALING BY FAITH, WITH REFERENC TO A VISIT TO THE GROTTO OF LOURDES.

By GEORGE BUCHANAN,
PROFESSOR OF CLINICAL SURGERY IN GLASGOW UNIVERSITY.

Public attention has recently been directed to certain alleged cures which are said to have been performed by members of the Salvation Army, as it calls itself. These recoveries are stated to have taken place after prayer and the laying on of hands. It is not claimed that anyone has obtained the gift of working miracles; but it is claimed that through faith in the efficacy of the prayer the person so believing obtains the benefit of direct divine interposition. It is religious faith in the efficacy of the prayer that alone secures the desired result. The co-operation of the desire, will, and faith of the patient are necessary for the effect to follow. If, as frequently happens, there be a misgiving of the expected cure, it is set down to want of desire and faith. Mr. Spanton has taken the trouble to investigate a number of the alleged cases in which the affection said to have been cured was almost exclusively subjective—pain, dimness of vision, dulness of hearing called deafness, &c. So far as he was able to estimate, the improvement was not discernible by such tests as he was able to apply.

There is nothing in medical diagnosis more difficult than to distinguish between real and feigned disease. Even in such manifest things as alleged stiffness and powerlessness of joints it is not easy to detect assumed conditions. Anyone who has much experience of hospital practice, or has seen a little military service, knows how difficult it is to detect malingerers. When I was on duty in the camp hospital in the Crimea I had occasionally to examine men who asserted that they were unfit to return to duty owing to pain, stiffness, and want of power in their shoulder- and elbow-joints, and I sometimes failed to detect the imposture, till I got the assistance of a colour-sergeant who was one of my patients. By making them go through a certain amount of drill in the hospital tent, one or two forgot or omitted the sort of deficiency of movement which must have existed if the alleged affection was real. How much more deceptive when the symptoms are subjective.

I wish, however, to call attention to a class of cases, less numerous but more marked, in which there is a real abnormal condition, accompanied by all the symptoms and sufferings of structural disease, in which the patient loses sleep and appetite, and emaciates, and frequently dies of exhaustion, while all the time the disease is nervous and not organic, mental and not bodily. I believe that some such cases have been restored to health by what is called healing by faith in prayer. I know that many such have been apparently miraculously cured by a visit to the miracle grotto of Lourdes.

In the autumn of 1883, when on a tour in the Pyrenees, I paid a visit to this spot, now such a celebrated shrine of the Roman Catholic faith. At the mouth of the grotto, at which a vision of the Virgin is said to have appeared to a poor girl, Bernadette Soubirons, are suspended numerous crutches, splints, &c., said to have been left there by persons who came lame and walked away restored to the use of their limbs. I believe that some of these cases are sufficiently well attested to make it quite certain that a number of apparently miraculous cures of halt, lame, and decrepit persons have actually occurred there. And this fact, which cannot be denied, is used as an argument to prove that the grotto is the seat of direct divine interposition, and the water which flows from it is endowed with miraculous healing power. On reflecting on the credibility of the alleged miraculous cures, which are so often appealed to as a proof of the truth of the story, it is no argument against the belief in them that multitudes of the patients who have visited the grotto and used the water have been disappointed in obtaining a cure. One positive is worth a thousand negatives. The difficulty in such cases always will be to get well-authenticated cases reported on by unbiassed judges who are competent to investigate them. For myself I have no doubt that some of the persons who went lame and crippled were restored to the use of their limbs and were relieved from pains and aches

And if we admit some, the question of number does not affect the argument. With regard to partial deafness and dimness of vision which are among the ailments said to have been cured, so much depends on the assertions of the persons affected that I would place little reliance on them; but with regard to persons who have been lame and decrepit, and known as such to their friends, the fact of their leaving their crutches and walking away without help does seem astonishing and miraculous, and it is cases such as these which make the greatest impression. I believe that the simple visit to the grotto by persons who believe in it, and the whole surrounding of the place, might have such an effect on the mind that a sudden change of the nerve condition might result in immediate improvement in cases where there is no real change of structure, but where the malady is a functional imitation of organic disease. Such cases are familiar to all medical men, and are the most intractable they have to deal with, the disorder being in the imagination, and not in the part. To non-professional persons this assertion may seem an enigma. It is an enigma to medical men, but it is none the less true. But instead of pursuing this general statement I shall relate cases within my own experience.

It is rather a remarkable coincidence that on Oct. 2nd, 1883, within three weeks of my visit to Lourdes, I received a letter from a Mrs. F——, reminding me that some years before I had performed in her case a cure, instantaneous and to all appearance miraculous, and which she properly attributed to undoubting faith in my word. It is a very good illustration of the kind of cases to which I have been alluding, and of the power of mind over mind, and of the effect of imagination in simulating real disease.

Mr. F—— called on me in October, 1875, and requested me to visit his wife, who had been confined to bed for many months with a painful affection of the spine. When I went to the house I found Mrs. F——, a woman about thirty-one years of age, lying in bed on her left side, and her knees crouched up, that being the position which afforded most relief. She was thin and weak-looking, with a countenance indicative of great suffering. I was informed that for many months she had been in the same condition. She was unable to move her limbs, any attempt being attended with pain, and practically she was paralytic. She was not able to alter her position in bed without help, and this always gave so much trouble that she would have remained constantly in the same position if the attendants had not insisted on moving her, to allow of the bedclothes being changed and arranged. She had altogether lost appetite and had become dreadfully emaciated, and only took what was almost forced on her by her husband and friends. She had given up all hope of recovery, but had expressed a strong desire to be visited by me, in consequence of something she had heard from her husband connected with a health lecture he had been present at many years before. When I entered her bedroom, something in the way she earnestly looked at me suggested the idea that I might have some influence over her supposing it to be a case of hysterical spine simulating real spinal irritation and sympathetic paralysis. The story I got was not that of real organic disease of the spine or cord, or limbs; and I at once resolved to act on the supposition that it was subjective or functional, and not depending on actual molecular change or disintegration. I went to her bedside and said, suddenly, "I cannot do you any good unless you allow me to examine your back." In an instant she moved slightly round and I examined her spine, running my finger over it, at first lightly, then very firmly, without her wincing at all. I then said, "Get out of bed at once." She declared she could not move. I said, "You can move quite well, come out of bed," and gave her my hand, when, to the surprise of her husband and sister, who looked perfectly thunderstruck, she came out of bed with almost no help at all and stood alone. I then said: "Walk across the floor." Now without demur she walked without assistance, saying, "I can walk quite well, I knew you could cure me; my pains are gone." She then went into bed with very little assistance, lay on her back, and declared she was perfectly comfortable. She was given a glass of milk, which she took with relish, and I left the house, having in a few minutes performed a cure which to the bystanders looked nothing short of a miracle. For many years I heard nothing of Mrs. F——, when on October 2nd, 1883, I got the letter referred to, and shortly after the patient herself called at my house. In February, 1885, she again called on me. She is at present in fair health, not robust, but cheerful and contented. She says she never altogether regained her full strength, but as an evidence that she is not feeble or unable for a good deal of exertion, I may state that she now lives about five miles from my house, and she made her way alone, partly by omnibus, partly by tramway, and the rest on foot.

About two years ago a carriage and pair arrived at my door from the country. In it was a woman about twenty-five years of age, her limb bound up in a splint and resting on the seat opposite to that on which she sat. She was accompanied by her father and brother, who, with the assistance of the coachman, carried her into my house and laid her on the sofa of my consulting-room. She told me she had been confined to bed for four or five months with disease of the knee, but that it had lasted longer than that. It was only the last few months that her medical attendant had enjoined absolute rest in bed, had used blisters and other applications, and had in the end secured it from movement by the application of a splint. She said the pain was very severe, increased on any movement, and was worse at night. There was little if any swelling, but the symptoms were very characteristic of disease of the cartilages of the knee-joint, and undoubtedly she was being treated for that affection. On manipulating her knee whilst I engaged her attention by asking her questions, I became aware that she did not shrink from my touch, as she did when I asked her if she felt pain on pressure; and I was soon convinced that I had to do, not with an organic disease of the joint, but with that strange, painful, and intractable condition which, for want of a better name, we call "hysterical knee." I turned to her and said decidedly, "Your knee is quite well; get up and walk." She at first objected, in consequence of the fear of pain; but when I said, "You will walk quite easily without pain," she got up and, to her own surprise, as well as that of her companions, she walked across my room, saying, "You are quite right; I have no pain, and my knee is cured." A few minutes after she left the house, got into the carriage without much assistance, and drove away. About a month afterwards a person from the same country town had occasion to call on me and spoke of the extraordinary instantaneous cure. I asked if he knew how the person was, and he said she was a friend of his own, and just the day before he had seen her walking as if nothing was wrong with her limb. And he knew that she had been confined to bed with her knee for months.

I cannot pretend to explain these two cases; they are certainly not miracles. But they are just as miraculous as any of the cures alleged to have been performed at Lourdes or elsewhere. Of the many thousands annually attracted to that spot a great number must be cases analogous to those I have related, and the alleged sudden cures are not more numerous in proportion than those which have occurred in medical practice. There are, however, some cases which cannot be included along with those to which I have referred. Cases in which instantaneous cure has taken place, or is alleged to have taken place, in such maladies as ulcers, sinuses, and easily recognised disintegration of bone. Such examples have been reported and vouched for by several French medical men and are referred to in an article in the *Nineteenth Century* for 1882; and I admit that the explanation is not applicable to them. I have not seen the official reports of the cases, so that I cannot admit or deny their accuracy. If there is no fallacy in them, they are beyond my understanding. But in the meanwhile the purpose of my paper is served if I have shown that many sudden cures may be explained without admitting miraculous interposition.

Glasgow.

UNIVERSITY OF CAMBRIDGE.—At a congregation on June 11th the following were appointed examiners:—Third M.B. Examination: Dr. Octavius Sturges, Emmanuel; Dr. Norman Moore, St. Catharine's; Dr. Donald Macalister, St. John's; Dr. W. O. Priestly, Edinburgh. Surgery: Mr. Christopher Heath, F.R.C.S., Mr. David Colley, Trinity. State Medicine: Dr. Alfred Carpenter, London; Dr. F. B. de Chaumont, Edinburgh; Dr. Hubert Airy, Trinity; Sir Charles A. Cameron, President of the Royal College of Surgeons, Ireland. Also the following degrees were conferred:—Doctors of Medicine: Audley Cecil Butler, Trinity; Jamieson Boyd Hurry, St. John's. Bachelors of Medicine: Richard Henry Emerson, Clare; John Mitchell Clarke, Charles Scott Sherrington, Dudley Charles Trott, Gonville and Caius; Walter Spencer Anderson Griffith, Downing.

WHY DOES SALICYLIC ACID CURE RHEUMATISM?[1]

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,
DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

WHY does salicylic acid cure rheumatism? This, gentlemen, is the question I venture to bring under your consideration to-day. The brilliant success which attends the proper administration of the remedy in this disorder is at once sufficient to fascinate us; there is something so decided in its action, so marked in the way it controls the heat and nervous and vascular excitement, and in the rapidity with which the great pain and swelling of the joints decline, that we are impelled to pause and think and question ourselves, How is this possible? Here is a disorder which under different treatment may exist for weeks stationary, so to speak, in its intensity, the great heat and nervous and vascular excitement, and pain and swelling exactly of the same amount to-day as they were weeks ago; a disorder which less than fifty years since was said to be "often such in itself and such in its appalling incidents as to need from time to time that medicine should put forth the full compass of all its powers. Every organ or system of organs which either directly or indirectly can receive the impression of remedies are from time to time called to bear all that they can possibly endure; and it is often only when the powers of medicine are pressed even to the verge of destroying life that life is saved."[2]

And now, by means of our new remedy, the disease seems to be curbed and checked and controlled. Surely we have here one of the greatest triumphs of the practical medicine of to-day, and a subject therefore worthy of consideration and investigation. And as the mind dwells upon the subject, points which physiology and pathology have left obscure rise up and add intensity to our interest and give increased importance to our inquiry; for we see how far beyond this one disease the interest reaches, how many are the problems it would help to clear up, and we become the more eager to obtain an answer. Can the answer be given? Let me take you to the bedside, and let us learn first of all what is to be gathered from practical medicine. Here is an example, such as will have occurred in the experience of each individual whom I am addressing. You are called to a patient who after a chill, and feeling out of sorts for two or three days, wakes up in the morning with one of the joints stiff and tender; soon afterwards it swells, and motion causes pain. Other joints now become affected; the knees, wrists, elbows, ankles, and the smaller joints of the hands and feet. There are pain, tenderness, increased heat, swelling, and redness of the skin. The slightest motion becomes insupportable, even vibration of the room or of the bed causes suffering. There is more or less febrile movement, the temperature ranging from 102° to 104° or higher, generally more or less sweating, the odour of which is characteristic. The tongue is coated; thirst is generally a marked symptom. These symptoms, varying in intensity, have perhaps continued many days. With or without the administration of a purgative, as the occasion requires, you place the patient fully under the influence of salicylic acid, and in from forty to sixty hours, not unfrequently in a shorter time, the pains in the joints have subsided, the limbs can be freely moved, and the bodily temperature has reached the normal condition. And this example may be indefinitely repeated. Patients presenting the same sort of history, the same picture of suffering and high fever, numerous joints swollen and intensely tender, and all this you subdue completely and effectively with your remedy in a few hours or days. But more than this—and here the remedy shows its signal power,—in no case of rheumatism that has come under my care during the last five years either in hospital or private practice has there been, where the heart was previously sound, any cardiac complication, such as endocarditis or pericarditis, developed. If this can be maintained and proved, we have indeed in our hands a most potent remedy. Cardiac complications constitute the chief danger of acute rheumatism, and the danger, if the disease is taken in hand soon enough, may with our new remedy be averted.

And what are the conditions, then, which in acute cases will ensure success in the administration of the remedy?

First, the true salicylic acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialysed and purified. An impure acid will very quickly produce symptoms closely resembling delirium tremens.

Secondly, give the acid without any alkali or base. A very good form is to mix 100 grains with 15 of acacia powder and a little mucilage. Allow the mass to stand and harden, and then divide into 30 pills.

Thirdly, place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance—i.e., buzzing in the ears or headache, or slight deafness; with the development of these symptoms the temperature and the pain in the joints will begin to decline. To an adult I generally administer three doses of 20 grains (six pills) at intervals of an hour, and if the head remains unaffected, a fourth dose at the end of another hour; and then repeat the 20 grains every four hours until the physiological effect of the remedy shows itself. In the majority of cases from 80 to 100 grains are enough. In severe cases 140 to 150 may be required. Afterwards about 80 grains a day are sufficient, and as the temperature declines smaller quantities will develop their physiological effects, 60 or even 50 grains being then sufficient to produce cerebral disturbance. It would appear that as long as the rheumatic poison is circulating in the system, the physiological effect—that is, the effect it produces in the healthy organism—does not show itself; acting as an antidote, the greater the amount of poison the larger must be the dose of the remedy; but as soon as the formation of the *materies morbi* is stopped, then the excess of the remedy acts as it would in the healthy organism and its peculiar physiological effects are developed. It is a very striking illustration of the difference between the therapeutical effect of a remedy and its physiological action.

Fourthly, give the patient from 40 to 80 grains daily for ten days after all pain and pyrexia have passed away.

Fifthly, let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. On the other hand, if the patient has meat and soup, you may look forward with fair probability to a relapse.

Sixthly, take care to maintain a daily and complete action of the bowels. Calomel is the best purgative, from 2 to 5 grains at night, followed in the morning, if necessary, with a saline draught. This is the most important adjuvant to the action of salicylic acid, and I will presently explain to you why this is the case. The benefits resulting generally from the so-called purgative plan of treatment have always been recognised by the older physicians as striking and satisfactory.

Seventhly, let the patient be enveloped in a light blanket, and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient, not, as in former times, to sweat the poison out of him, and the cooler he is kept the sooner will the temperature be lowered.

These are the seven rules upon which I have acted. I have given the true salicylic acid where there have been both aortic and mitral mischief; and I have also given it in rheumatism complicated with pericarditis, and as yet I have seen no bad result from it. Of course in cases of pericarditis, accompanied with delirium, the use of the remedy requires caution; you cannot tell when the system is saturated with the remedy, and you must therefore trust to smaller doses and other means for controlling the disease. Further, if pericarditis or endocarditis, pneumonia, or pleurisy have been developed, the remedy is powerless over the mischief which is done; it will neutralise the poison producing the mischief so as to stop its extension, but the inflammatory exudations will undergo their usual changes unabbreviated in their course.

And what is the poison? One of the most prominent features in an acute case of rheumatic fever is the formation of lactic acid in large quantities; and the so-called lactic acid theory of the causation of rheumatism is one which has got a very firm hold of the minds of many physicians, probably of most of those whom I have the honour of addressing. It was the view with which I started four or five years ago when I resolved to try and help to unravel some of the mysteries of the disorder, and a view which I have held till very recently. Nevertheless, I hope to show now that though lactic acid has much to do with the symptoms, it is not the chief substance which causes the disease, nor that upon which salicylic acid chiefly acts as an antidote.

---

[1] An Address delivered before the combined meeting of the East Anglian, South Midland, Cambridgeshire, and Huntingdonshire branches of the British Medical Association, held at Cambridge, June 12th.

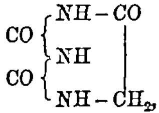
[2] Dr. P. M. Latham's Works, Sydenham Society, vol. i., p. 112.

It is the excessive formation of glycocine and of uric acid in the tissues that develops the symptoms of rheumatic fever, and salicylic acid cures the disease by combining with the antecedents of these bodies and preventing their formation.

Last year, as some of you are aware, I published a short paper on uric acid,[3] in which I endeavoured to show that this substance resulted from the conjugation of glycocine with urea, or its antecedents, forming the compound.

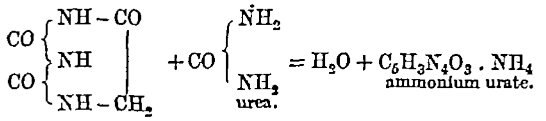
$$\left.\begin{matrix}\mathrm{CO}\\ \mathrm{CO}\end{matrix}\right\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{NH}\\ \mathrm{NH-CH_2-COOH};\end{matrix}$$

that is, a compound containing one more molecule of CONH than hydantoic acid, and allied to biuret and allophanic ether. This substance dehydrated would form



$$\left.\begin{matrix}\mathrm{CO}\\ \mathrm{CO}\end{matrix}\right\{\begin{matrix}\mathrm{NH-CO}\\ \mathrm{NH}\\ \mathrm{NH-CH_2},\end{matrix}$$

which, like hydantoin, being soluble in the blood, passes on to the kidneys, and is there conjugated with another molecule of urea, and forms ammonium urate.



$$\left.\begin{matrix}\mathrm{CO}\\ \mathrm{CO}\end{matrix}\right\{\begin{matrix}\mathrm{NH-CO}\\ \mathrm{NH}\\ \mathrm{NH-CH_2}\end{matrix} + \underset{\text{urea.}}{\mathrm{CO}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{NH_2}\end{matrix}\right.} = \mathrm{H_2O} + \underset{\text{ammonium urate.}}{\mathrm{C_5H_3N_4O_3\,.\,NH_4}}$$

which is excreted; but a portion overflowing from the kidney into the general circulation, and meeting with soda in the blood, is converted into sodium urate.

I there maintained that whereas in diabetes the essential fault consists in the inability of the system, either in the liver or elsewhere, to effect the metabolism of glucose, in gout the fault consists in the imperfect metabolism of glycocine, or amido-acetic acid. Glycocholic acid, as we know, is one of the constituents of the bile, and poured out into the duodenum performs its function in digestion, and is there resolved into cholic acid and glycocine; the latter being reabsorbed into the liver and transformed, and a corresponding amount of nitrogen being subsequently eliminated as urea by the kidneys.

We know that by atropine we can by paralysing the end organs of the nerves modify the functional activity of the submaxillary gland, and by urari we can in the same way modify the functional activity of the muscular tissues. Further, that the central nervous system possesses the power of varying the functional activity of the tissues, and we can readily understand that if this functional power of the liver were lessened in a certain degree, the glucose conveyed from the portal system would pass unchanged through the liver into the general circulation and produce the symptoms which accompany diabetes. If the power were lessened in a different degree, then glycocine would no longer be transformed by the liver, but, being conjugated with other substances, give rise to uric acid, which acting upon the portion of the nervous system which controls the nutrition of the joints would under certain circumstances give rise to the phenomena of what we call a gouty paroxysm. Here, then, we have diabetes and gout both commencing, so to speak, at the liver, and in such cases the diabetes would be relieved by the avoidance as much as possible of farinaceous and saccharine food. The gout would be prevented or relieved by a diet largely farinaceous and by eliminating the glycocine from the system and by giving as little nitrogenous food as possible.

Now, what happens when salicylic acid is administered internally? It passes off by the urine as salicyluric acid—that is, it has combined in its passage through the system either with glycocine or its antecedent, for on treating salicyluric acid with fuming hydrochloric acid, it is resolved into salicylic acid and glycocine.

$$\underset{\text{salicyluric acid.}}{\mathrm{C_9H_9NO_4}} + \mathrm{H_2O} = \underset{\text{salicylic acid.}}{\mathrm{C_6H_4}\left\{\begin{matrix}\mathrm{HO}\\ \mathrm{COOH}\end{matrix}\right.} + \underset{\text{glycocine.}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{COOH}\end{matrix}\right.}$$

Consequently in the system, by *seizing* either upon glycocine or its antecedent, salicylic acid takes away an essential constituent of uric acid, and so prevents the formation of this body.

I have referred to the antecedent of glycocine. Let me say a word about this. In a paper recently published[4] I have endeavoured to show that albumen is a compound of cyan-alcohols united to a benzene nucleus. These cyan-alcohols have been prepared in the laboratory, with the exception of the lowest in the series $\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$, which requires *for its preparation formic* or methylic aldehyde, a substance which has not yet been obtained in a pure state. From the cyan-alcohols the corresponding amido-bodies, leucine, alamine, &c., have been artificially prepared. Judging from analogy, therefore, by treating the cyan-alcohol $\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$ with ammonia, we should form the cyanamide $\mathrm{CH_2}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{CN}\end{matrix}\right.$ which, hydrated with acids or alkalies, would form the amido-acid glycocine

$$\underset{\text{cyan-alcohol.}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.} + \mathrm{NH_3} = \underset{\text{cyanamide.}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{CN}\end{matrix}\right.} + \mathrm{H_2O}$$

$$\underset{\text{cyanamide.}}{\mathrm{CH_3}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{CN}\end{matrix}\right.} + 2\mathrm{H_2O} = \underset{\text{glycocine.}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{COOH}\end{matrix}\right.} + \mathrm{NH_3}$$

By referring to my paper you will see that it is also from the molecules of $\mathrm{CH_3}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$ attached to the benzene nucleus that I think creatine is derived; and that by changes in it and condensation, urea is formed, and the next cyan-alcohol higher in the series, $\mathrm{CH_2\,.\,CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$ by the hydration of which, as well as by the hydration of $\mathrm{CH_3\,.\,CH}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$ lactic acid would be formed.

$$\underset{\text{cyan-ethylic alcohol.}}{\mathrm{C_2H_4}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.} + 2\mathrm{H_2O} = \underset{\text{lactic acid.}}{\mathrm{C_2H_4}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{COOH}\end{matrix}\right.} + \mathrm{NH_3}$$

It is with this body $\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.$ that salicylic acid (as I would suggest) combines in its passage through the liver. If that substance were combined with cholic acid, we should have

$$\underset{\substack{\text{methene}\\ \text{cyan-alcohol.}}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.} + \underset{\substack{\text{cholic}\\ \text{acid.}}}{\mathrm{C_{24}H_{40}O_5}} = \underset{\substack{\text{glycocholic}\\ \text{acid.}}}{\mathrm{C_{26}H_{43}NO_6}};$$

and glycocholic acid acted upon by alkalies is converted into cholic acid and glycocine.

$$\underset{\text{glycholic acid.}}{\mathrm{C_{26}H_{43}NO_6}} + \mathrm{H_2O} = \underset{\text{cholic acid.}}{\mathrm{C_{24}H_{40}O_5}} + \underset{\text{glycerine.}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{NH_2}\\ \mathrm{COOH}\end{matrix}\right.}$$

Now, if salicylic acid, when it passes from the alimentary canal to the liver, combines with the cyan-alcohols, we should have

$$\underset{\substack{\text{methene}\\ \text{cyan-alcohol.}}}{\mathrm{CH_2}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN}\end{matrix}\right.} + \underset{\substack{\text{salicylic}\\ \text{acid.}}}{\mathrm{C_6H_4}\left\{\begin{matrix}\mathrm{OH}\\ \mathrm{COOH}\end{matrix}\right.} = \left.\begin{matrix}\mathrm{CH_2}\\ \mathrm{C_6H_4}\end{matrix}\right\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN\,.\,OH}\\ \mathrm{COOH}\end{matrix}$$

a formula of the same character as the molecules of living albumen. As this passes from the living tissue, the CNOH would be transformed into CONH, an imido-body, and the

$$\left.\begin{matrix}\mathrm{CH_2}\\ \mathrm{C_6H_4}\end{matrix}\right\{\begin{matrix}\mathrm{OH}\\ \mathrm{CN\,.\,OH}\\ \mathrm{COOH}\end{matrix} \text{ would become } \underset{\text{salicyluric acid.}}{\mathrm{CH_2(NH\,.\,C_7H_5O_2)COOH}}.$$

If the salicylic acid has a stronger affinity for the cyan-alcohol than cholic acid has, then the combination would prevent the formation of glycocholic acid, and therefore of glycocine, so that by the combination of salicylic acid in the liver, either with methene cyan-alcohol or by its conjugation with glycocine, as the latter is reabsorbed from the alimentary canal, the formation of uric acid in the system would be lessened. *(To be concluded.)*

NOTES OF VISITS TO CONTREXÉVILLE AND ROYAT-LES-BAINS.[1]

BY F. R. CRUISE, M.D. UNIV. DUB.,
PRESIDENT OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

MR. PRESIDENT AND GENTLEMEN,—It is well known to all physicians of experience that one of the most powerful agents we possess in the treatment of many chronic ailments is the use of mineral waters, especially when taken at their sources. However, if it be needful to prescribe the most efficacious drugs for each case we meet, it is no less important to select for each of our patients the mineral water best suited to his disease. To do this requires a somewhat special training and experience, not easily attainable. It is most important, both for patient and physician, that no mistake should be made in the choice, as a visit to a thermal station is not unfrequently a very laborious and expensive undertaking. For these reasons I venture to make the present communication to the Academy of Medicine in Ireland, in the hope of giving to others some information, derived from personal exeprience, of two celebrated French watering-places—namely, Contrexéville and Royat-les-Bains.

A brief history of the circumstances which led to my visiting Contrexéville in the year 1877 may add to the interest of the subject, and therefore I will relate it. Just fourteen years ago Sir George Porter and I attended a young lady (Miss M.) who suffered severely from chronic cystitis. The origin of the disease was obscure, but, from our knowledge of the patient's constitution, we inclined to the belief that a strumous diathesis was to blame. I regret to add that we failed to cure her. After some time Miss M.'s mother took her abroad, and while in Paris consulted the late Dr. Acosta about her case. Dr. Acosta recommended a visit to Contrexéville, and a course of the waters and baths there. His advice was followed, and the result was a perfect cure. I need hardly say that this rapid cure of so obstinate a disease, by a visit to a mineral water of which we had never even heard, made a very strong impression upon Sir George Porter and on me, and we resolved to profit by the experience. Before adverting to the many cases in which we advised a visit to Contrexéville, I may here record the fate of Miss M. A few years subsequent to her cure of cystitis she died suddenly. I learned that her death was preceded by very violent headaches. Although neither Sir George Porter nor I had attended Miss M. during the fatal illness, the family wished us to be present at the post-mortem examination, which was deemed advisable on account of her sudden and unexplained death. The examination showed that the cause of death was a large effusion of blood at the base of the brain. The membranes and adjacent cerebral substance were found extensively infiltrated with tubercular deposits. Sir George Porter and I felt anxious to ascertain the condition of the bladder, which had formerly been so much affected, and accordingly we examined it. As a result we found that organ and all its appendages, kidneys included, perfectly healthy.

Shortly after our favourable experience of the effects of Contrexéville in Miss M.'s case, Mr. C., an elderly gentleman of high position in the legal world, came under Sir George Porter's and my care. His case was one of chronic cystitis, the result of stricture and prostatic disease. The dilatation of the stricture gave but little relief to the cystitis and accompanying sufferings. So we advised him to go to Contrexéville. He went there two summers consecutively. His case was not a hopeful one for cure, but he derived very marked relief, and his life was evidently prolonged considerably.

The next case I shall allude to was that of a distinguished ecclesiastic, the President of one of the Provincial Colleges of Ireland, who suffered intensely from renal colic, cau by oxalate of lime gravel. His cure, accomplished by a visit of three weeks (in 1877), was complete and permane A similar case, in the person of a well-known and mu respected Dublin merchant, occurred (in 1883) within m own experience.

In the summer of 1882, Dr. James Little asked me to s a medical *confrère* (Dr. L.), who was quite broken down b chronic pyelitis. We decided to send him to Contrexévill where he derived much relief; and finding this cold, da climate unendurable, he emigrated to Australia, whence h sends me good accounts of his health and progress.

Without going into details of cases, it will be sufficient t state in brief that since I have known of Contrexéville have either sent there, or treated here with the import waters, most of the obstinate cases of irritable bladder o cystitis which have come into my hands, and that all ha derived benefit, and the more hopeful quite a satisfacto result. It so happens that my endoscopic studies hav brought under my care a large proportion of cases of urina disease, so that my experience has been somewhat extensiv When first I learned the therapeutic value of Contrexéville I sought in various directions for information concerning i and encountered much difficulty in my research. Althoug so celebrated in France and on the Continent, this watering place appeared unknown in England, and, with the exceptio of the brief notice of it in the French manual on miner waters by Dr. Constantine James of Paris, I could obtain no details. At last one of the patients whom I had sent thithe brought me two essays on the subject: one by the late Dr. Victor Baud, who had practised there for a quarter of a century, and another, more brief, by Dr. Tamin-Despalles, who was then in practice at these waters. More recently I have found an essay on the subject by Dr. Debout d'Estrées, the Government inspector of the station, which, on the whole, is the most satisfactory I know of.[2]

Wishing much to see Contrexéville, and urged to do so by Sir George Porter, I took an opportunity while at leisure in Paris, in the autumn of 1877, to run down there and make a personal visit. Taking the night mail from Paris by the Chemin de Fer de l'Est, I reached Neufchâteau, in the Vosges district, about six o'clock in the morning. Having breakfasted, I hired a *voiture* and drove to Contrexéville, a lovely drive of about fifteen miles, through a pretty mountainous country, not unlike our own county Wicklow. I may observe here that nowadays the train from Paris goes straight through to Contrexéville, making the journey shorter and easier than formerly. On my arrival I was most hospitably received by Dr. Tamin-Despalles, who showed me all that was to be seen, and explained the uses and effects of the waters. I regret much to say that this experienced practitioner has since died after a long attack of brain disease. His place is ably filled by several other physicians of eminence, amongst whom I may specially mention Dr. Debout D'Estrées, who has treated several patients I sent to him with judgment and success. I had the pleasure of making his personal acquaintance in the year 1883. To show how little was known of Contrexéville, except on the Continent, I may mention that Dr. Tamin-Despalles told me, in 1877, that so far as his knowledge went, and it extended over a long term of years, I was the first English-speaking physician who had ever visited it. Since that time it has come under marked notice, and has been visited by many of our Irish, English, and American *confrères*; however, as I have not seen any account of their visits in our language, I think a note of my experiences may interest the members of the Academy of Medicine in Ireland.

I found Contrexéville a pretty little town, or rather village, made up for the most part by the hotels and boarding-houses which accommodate the great influx of patients who come to it for the season from May until about Sept. 15th. In former days it belonged to the kingdom of Lorraine, but now it is in the department of the Vosges. Situated on the river Vair, in a valley open from north to south, it is placed at a height of over 1000 feet above the sea level. Its situation explains the sudden changes of temperature to which it is subject, especially in the morning and evening. This fact must be borne in mind by visitors, who should always be provided with woollen garments, even in the height of summer. Though the waters of Contrexéville have been locally celebrated time out of mind, they were only made known to the medical world in

---

[1] Read before the Academy of Medicine in Ireland, May 29th, 1885.

[2] This guide book can now be had, in English, from Messrs. Churchill, of New Burlington-street.

1760, by a report read before the Society of Science and Arts of Nancy, by Dr. Bagard, physician to Stanislaus, King of Lorraine. A short extract from this quaint report will show that even at that distant time Contrexéville was resorted to by patients suffering from gravel, bladder diseases, gout, and liver complaints:—

"The mineral waters of Contrexéville are a sovereign remedy in diseases of the kidneys, of the ureter, of the bladder and the urethra, stone, gravel, glair, suppuration. We can assert that these waters are efficacious against the stone, which they loosen and drive out of the bladder, when the stone is not of a considerable size; that they dissolve and break larger stones, when the latter are chalky. We keep a list of patients of all ages who during several years have got rid of a stone through the effect of these waters. They prevent fresh attacks of gout by restoring the suppleness of the nerves, and of the membranous parts which the disease has dried up. As these waters contain ferruginous matter, a mineral acid and soap, they will be very useful in cases where the bile becomes too thick, and where the liver is obstructed—the more so as they are purgative."

Dating from the time of Dr. Bagard's report, we find the celebrity of Contrexéville steadily growing. Analysis upon analysis has been made of the waters—the Government has taken the station under its protection. Capitalists have expended large sums in making the place attractive to visitors, and year by year the number of these visitors has increased, so that now, owing to the crowds, it is necessary to secure accommodation in advance before venturing to undertake the journey. The accommodation at present is quite first-rate. There are capital hotels and boarding-houses to suit various means; also a well-regulated *établissement* for baths, douches, &c., a very pretty park, with suitable amusements, Casino, theatre, covered promenades, music, reading-rooms, &c. It is right to add that travellers who seek amusement alone are likely to be disappointed. The place is remote and somewhat dull, the patients who go there not young or lively; but the cures are numerous and remarkable, and the patients generally very well satisfied. I was greatly struck in observing the wisdom of the French Executive, which, like all other Continental Governments, takes under its guardianship all places possessing mineral waters of value, developing their utility, and doing full justice to their virtues and capabilities; a contrast very humiliating to anyone familiar with the neglect exhibited by our Government towards places similarly gifted in Great Britain and Ireland.

Contrexéville is prettily situated in the heart of the Vosges mountains, surrounded by agreeable walks and drives, and within easy reach of many interesting places. Amongst others I may mention Domrémy, the birthplace of Joan of Arc; Mirecourt, a flourishing town, celebrated for the manufacture of musical instruments; Neufchâteau, the valleys of Viviers and Bonneval, the baths of Plombières, and similar places. Trips to these various resorts pleasantly fill in the leisure hours of the patients staying at Contrexéville.

As already mentioned, I visited the different springs, and ascertained their properties. Four principal springs are used, which I name in the order of their importance—namely, the Pavilion, the Prince, the Quay, the Sovereign. A fifth, named Le Cler, is also used, and its water exported, but it is weak compared with the Pavilion. All these springs are cold. The Pavilion may be taken as the typical and most important water. I give here a table, showing the result of M. Debray's analysis.

Analysis of the Pavilion Water.

Free carbonic acid	0·080
Bicarbonate of lime	0·402
„ magnesia	0·035
„ iron	0·007
„ lithium	0·004
Sulphate of lime	1·165
„ soda	0·236
„ magnesia	0·030
Silica	0·015
Chloride of potassium	0·006
„ sodium	0·004
Fluoride of calcium	traces
Arsenic	traces
	2·384

While we may take the Pavilion water as the most important and typical in its composition and effects, it is right to observe that the other springs are similar, on the whole, with some variations. Thus the Prince is richer in iron, and hence of great repute in the treatment of anæmia and diseases of females. According to Dr. Victor Baud it is specially efficacious in functional sterility. The Quay Spring contains more magnesia, and is particularly suited to the gouty. The Sovereign is much weaker than the others, and contains no iron, or at all events none worth notice. Le Cler resembles the Pavilion, but is weaker. I draw attention to this fact as it is now imported, but it is by no means as efficacious as the Pavilion. It is very important to observe that these waters bear carriage well, the only difference observable in the analysis made at the springs and after importation is that the latter show a certain falling off in strength.

My friend Dr. Tichborne, who has lately brought out an important work on mineral waters, in conjunction with Dr. Prosser James of London, was kind enough, two years ago, to place in my hands the results of his analysis of the imported waters of Contrexéville. According to his researches the solid constituents of the imported water amount to 166·7 grains per gallon, as against 229·5 found in the water fresh from the spring. Le Cler water shows only 149 grains per gallon.

It will be seen from the foregoing analysis that the spring belongs to the class of calcareo-sulphated waters—that it is alkaline, with a preponderance of salts of lime, that it contains aperient salines in the form of sulphates of soda and magnesia, also iron and arsenic, and traces of fluoride of calcium. It holds, moreover, sufficient free carbonic acid to make it bright and pleasant to the taste, when fresh from the source, thus masking its somewhat inky flavour. Its effects, when used internally, may be anticipated. It is, first, diuretic; secondly, laxative; and, thirdly, tonic. When taken in suitable doses it purges gently, improves the appetite, stimulates the circulation and skin, promotes the flow of bile, and especially it increases the urinary secretion in a very remarkable manner.

It is upon the urinary organs that the water of Contrexéville exercises the most powerful effect. It acts rapidly, producing a diuresis far in excess of the quantity of fluid ingested; it dissolves the mucus met with in the passages, and loosens and carries out small concretions. It has been observed to subdue quickly excessive acidity of the urine, clearing it remarkably of deposits, and, strange to say, in certain cases it is found to restore alkaline urine to its normal acidity. This seemingly paradoxical effect is due to its efficacy in curing morbid conditions of the urinary mucous membranes, which so often lead to ammoniacal decomposition, and consequent alkalinity of the urine. Its effects in cases of gravel and stone are remarkable. When the calculi are small, they are frequently washed out bodily by the diuresis. When large and soft, they are disintegrated and broken up to such an extent that some actual cures have been recorded; but the more common effect of Contrexéville water on large calculi is to strip them of mucous and phospahtic coatings, thus exposing the central calculus in its rough outline, and increasing the calculous symptoms. In this way the waters act as a valuable test, quickly revealing the presence of the stone, and compelling the patient to seek surgical aid, and waste no time in hesitancy, the too frequent result of procrastination, due to the fluctuation of symptoms. In cystitis, whether essential or symptomatic, the waters of Contrexéville are useful beyond all controversy, often curing the former, and mostly alleviating the latter cases, even when all other remedies have failed. I can speak with confidence on this subject, from an experience extending over fourteen years. The highest Continental authorities are agreed upon the therapeutic value of Contrexéville waters in urinary diseases. As I stated before, my knowledge of their utility arose from Dr. Acosta of Paris sending thither a case which had long resisted other treatment, and both the late Dr. Civiale, a specialist of European fame and historical celebrity, and Dr. Durand-Fardel, another specialist on the subject of mineral waters, speak in the highest praise of them. Dr. Civiale particularly advised their use in cases of atony of the bladder, arising from long-standing stricture, cystitis, and following the operation of lithotrity.

The essential difference observable between the Contrexéville waters and those of other alkaline sources, such as Vichy, Vals, and so forth, is that they are tonic, and thus, while beneficial to the local ailments, are, at the same time, restorative of the general health and strength. Such a combination of virtues cannot, by any means, be affirmed regarding many other alkaline waters.

Besides their internal administration, the waters of Contrexéville are also used externally in baths, douches, &c. I have some doubts of their possessing any very powerful effect when applied to the skin, except perhaps as a stimulant in douches, and thus an adjuvant to their internal exhibition; all the more so, as I observed at the time of my visit that the waters, when heated, freely deposit the solid ingredients, lining the boilers with thick incrustations.

Although my principal object in this paper is to explain the value of the waters of Contrexéville in diseases of the urinary organs, I may be allowed to notice briefly their utility in some other ailments.

First, in gout these waters will be found most serviceable especially in the chronic or atonic forms. This might be anticipated from their usefulness in calculous disorders, which are largely due to gout. In them we find properties at once diuretic, laxative, and tonic, fulfilling the most important indications for treatment. Moreover, being moderate in the degree of their mineralisation, they are much safer, especially for the weakly, than the waters of Vichy, Vals, Carlsbad, and other more powerful alkaline spas, which suit best for the plethoric. Trousseau, as also Charcot, dwells on this point in favour of Contrexéville.

Another class of cases in which these waters are found particularly useful are those in which the liver is congested and inactive from one cause or other, and the bile inspissated and tending to the deposition of concretions or gall-stones. Numbers of patients thus affected are sent by the French physicians to this station, and obtain remarkably favourable results. This, as in the case of gout, is just what we might expect from the composition and effects of the waters.

Another ailment in which Contrexéville waters are used with advantage is nocturnal incontinence of urine in children. I can speak decisively on this point from my own experience. I believe that in such cases the action of the water is twofold. In the first place, it corrects irritating conditions of the urine, and secondly, it restores tone to the organs. Whether this is the correct explanation or not, of one thing I am certain, that the use of the Pavilion water, as a diet drink, has cured a number of very obstinate cases.

Another disease in which Contrexéville water has been found very serviceable is diabetes. I do not mean to affirm that it will accomplish the cure of confirmed cases of diabetes with progressive wasting, but certainly in the group of patients who are gouty, and more or less diabetic, it materially reduces the glycosuria, and proves a useful adjunct to a regulated dietary. In this effect it closely resembles the famous American mineral water, the Bethesda.

To recapitulate: the waters of Contrexéville are mildly alkaline, especially from lime salts; saline, from sulphates of soda and magnesia; tonic, being ferruginous and arsenical, with traces of fluoride of calcium.

The diseases in which they prove useful are: Chronic affections of the urinary organs, especially when complicated by gravel, renal or vesical; gout, especially its atonic forms, the waters being tonic, and thus markedly contrasting with many other alkaline waters; diseases of the liver, especially those complicated by gall-stones; nocturnal enuresis in children; and diabetes, especially when associated with gout.

Let me add a word as to the use of the imported waters of Contrexéville. I advise the Pavilion spring, and none other. Of this I give half a bottle daily as a diet drink, either with milk, wine, or spirit, as otherwise indicated. Watching the effect I increase the quantity up to a whole bottle, but have not exceeded that amount. As to the method of using these waters at the Springs, I do *not touch* the subject. Taken fresh they are far too powerful to be used without the regular supervision of a physician familiar with their employment. Under such direction I believe they will be found an invaluable adjunct to the resources of the practical physician and surgeon.

(*To be concluded.*)

TAUNTON SANITARY HOSPITAL.—An honorarium of [illegible] guineas has been presented to the medical officer (Dr. [illegible]) and one of 30 guineas to the matron (Miss [illegible]) of this institution, for their services during the recent outbreak of small-pox, when 171 cases were admitted into the hospital. The salary of each has also been raised [illegible] £5 per annum respectively.

OVARIOTOMY IN ROME.

BY J. HARRY THOMPSON, A.M., M.D.

THE following report is made on account of several points of unusual interest connected with the case before and after the operation.

Marguirata M——, Italian, aged twenty-seven years, consulted me for the first time in February, 1882, and gave the following history. She was married in October, 1879. Her first child was born ten months after; her labour was natural and convalescence perfect. A few months after the birth of her child she noticed a tumour in the left iliac fossa about the size of an orange. At first she experienced no discomfort from it, but latterly the tumour had increased rapidly, and was the seat of repeated attacks of severe pain, accompained by fever. For several weeks respiration had been rapid and difficult; she was unable to lie down, but slept in a half-sitting position. She stated that she had consulted several physicians, who had expressed the opinion that she was suffering from a uterine myoma, and advised her not to submit to any operation. Her general appearance was that of a woman about forty years of age, skin sallow, face haggard and indicative of bodily suffering. The abdomen was enormously enlarged, measuring forty-nine inches around the umbilicus, the feet and legs were œdematous, pulse 118, temperature *normal*. The tumour was regular in outline, very hard, and the fluid wave indistinct; but a careful examination satisfied me that she was suffering from cystic disease of the ovary. I advised her to submit to the operation for radical cure, but to this neither she nor her husband would consent. It was only after much persuasion that she would consent to be tapped. On Feb. 23rd the tumour was aspirated with a large-sized cannula, and forty-seven pounds of reddish-brown grumous fluid withdrawn. The operation was followed by no constitutional disturbance.

The patient gained flesh and strength rapidly, and at the end of one month was apparently in perfect health. She had lost the aged and worn expression so strongly marked when she first came under observation. She presented herself occasionally for examination, having been advised that in all probability the fluid would reaccumulate, in which event it would be necessary to remove the tumour before it should again seriously impair her health. It was not until the end of May that I detected the sac to be refilling.

In August I received a letter from her husband stating that she was nearly as large as before the tapping, and suffering much pain and inconvenience, and was very anxious for the operation to be performed. I was then at Viareggio on the Mediterranean, where there is an excellent hospital under the charge of a Catholic sisterhood. I sent for her to come immediately, with the intention of placing her there for the operation. In a few days she arrived, and, to my surprise, I found that she was nearly five months advanced in pregnancy. She was larger than most women at full term. The situation was critical and embarrassing. If the pregnancy went on, the sac would in all probability be ruptured. To attempt to relieve her by tapping would be very hazardous, as, owing to the thickness of the abdominal walls, it was impossible to define the outlines of the tumour or uterus. She was fully advised of the situation, and the induction of premature labour was recommended as being the safest procedure under the circumstances. This suggestion was acceded to, and on August 31st a fine piece of carbolised catgut was introduced into the uterus and left there. In forty-eight hours labour pains were strong and the os well dilated, and she was safely delivered of a male fœtus on September 3rd. In two weeks from the time of delivery she felt so well and was so much reduced in size that she would not consent to the operation. She returned to Rome in the latter part of the month, promising me that she would not again expose herself to the danger from which she had escaped.

I saw her again in November. The tumour was large, but gave her little inconvenience; her general health was good, and continued so until February, 1884. At this time her abdomen was as large as when she first came under observation. It was then arranged that the operation should be performed one week after the termination of her next menstrual period. The results of ovariotomy in Rome had been so generally fatal that I was particularly anxious to protect my patient from any possible source of contamination. An apartment was secured on the top floor of a new palace, where there was abundance of pure air and sunshine. The furniture, which had never been used, was limited to absolute necessaries, and everything made thoroughly aseptic. On March 20th she was removed to her new quarters, and placed in the charge of a trained nurse from St. Paul's Home. The patient's diet for three days before the operation was confined to Scotch oatmeal with cream for breakfast and supper, and broiled beefsteak and bread for dinner, with a glass of claret.

I performed the operation on March 24th, 1884. Dr. Drummond administered the anæsthetic (Billroth's compound of ether, chloroform, and alcohol), and I was ably assisted by Professor Pantaleoni, Dr. Bull, and Dr. Georgiana. I made an incision over the linea alba, one inch below the umbilicus and extending downwards five inches. The abdominal wall was unusually thick and very vascular. Eighteen ligatures were applied before the hæmorrhage was controlled. Upon dividing the peritoneum, the tumour as far as the hand could reach was found to be strongly adherent over all except the lower anterior part. To secure working room, it was necessary to extend the incision three inches above the umbilicus. Adhesions which would readily yield were broken down by the finger, and the sac was tapped with Spencer Wells' trocar. Unfortunately, the rubber tube running from the trocar was bent upon itself, and before it could be straightened some of the contents of the sac escaped into the peritoneal cavity. The omentum was largely adherent; it was tied in six parts, the ligatures cut short, and the omentum divided. The separation of the adhesions about the umbilicus was difficult and tedious, and much time was occupied in this part of the operation. The abdominal wall and the wall of the sac were so intimately incorporated that it was found impossible to separate them with the finger and handle of the scalpel, and a careful dissection had to be made with the knife, a portion of the wall of the sac being left adherent to the abdominal wall. The bleeding was profuse. The larger vessels were ligatured with fine carbolised silk, and the ends of the ligatures cut off short; the remainder were twisted, and the oozing points touched with Paquelin's cautery. The pedicle was broad and very vascular; Sir Spencer Wells' clamp was applied, and the stump thoroughly cauterised and dropped back. The abdominal cavity was then carefully cleansed from blood and cystic fluid, and I was about to close the wound when the stump was discovered to be bleeding freely. Fortunately, it was easily found and secured by a double ligature of stout carbolised silk, the ends of which were left outside. The cavity was again sponged out, and the wound closed by thirteen sutures of stout silver wire. The abdominal walls were loaded with fat, being nearly three inches thick; the sutures were made to include one inch of peritoneum on either side. The ends of the ligatures from the stump were brought out at the lower angle of the wound by the side of an half-inch rubber drainage-tube, which was passed down to Douglas' cul-de-sac, and secured by a large-sized safety pin. Lister's dressings were applied, and over all a many-tailed flannel bandage. When the patient was placed in bed the pulse was scarcely perceptible, and the temperature marked 97°. Bottles of hot water were applied to the feet, hands, and sides of the body, and brandy administered hypodermically. She had been under the continuous influence of the anæsthetic for three hours, and the peritoneal cavity was open and exposed to the carbolic spray for nearly the same time. By 8 P.M. reaction was well established. Pulse 112; temperature 99°. She complained of pain at the site of the wound and thirst. The catheter was passed, but there was no urine in the bladder. Half a grain of the watery extract of opium was ordered to be given every four hours, if the pain continued or the patient became restless, and ice to allay the thirst.

March 25th.—6 A.M.: Has passed a restless night, but has less pain. Pulse 112; temperature 98°. One ounce of dark-brown urine has been drawn during the night. 4 P.M.: Complains of dull pain in the head and much thirst. No urine in bladder. Ordered four ounces of effervescing lithia water to be taken every four hours, iced milk in small quantities, and opium to be continued if necessary.

26th.—10 A.M.: Pulse 110; temperature 100·2°. Tongue clean and moist; has passed a quiet night; feels tired, but has little pain. The dressings, being soiled, were removed under the spray, and the part redressed. The wound looked well, the edges being united. Light-brown serum was flowing freely through the tube and by the side of the ligatures. During the night about two ounces of olive-green urine had been drawn by the nurse. 9 P.M.: Pulse 104; temperature 99·6°. The urine drawn during the day was of the same character, and about three ounces and a half in quantity.

27th.—10 A.M.: Pulse 110; temperature 99°. The patient looks well, says she feels better, has no pain about the abdomen, but her head feels queer. Three ounces of bloody urine had been drawn during the night. The bandages and pad under her were soaked with serum, slightly discoloured but odourless. Fresh dressings were applied under the spray. Lithia water to be continued, iced milk for nourishment, and no opium to be given unless the patient should be restless. 10 P.M.: Pulse 100; temperature 98·5°. The patient sleeping. About four ounces and a half of urine had been drawn since morning visit, and still some blood in it.

28th.—11 A.M.: Pulse 100; temperature 98·5°. The patient quite cheerful. She has passed five ounces of urine during the night without blood, and much lighter in colour. The flow of serum continues very abundant. Fresh dressings were applied. Lithia water to be continued, and for nourishment milk and beef essence alternately. No night visit made.

29th.—9 A.M.: Pulse 104; temperature 98·2°. Patient looks anxious, complains of pain all over the abdomen, which is much distended. On removing the bandages I found them but little soiled, and no serum flowing from the tube, and but little by the side of the ligatures. Upon withdrawing the tube, which was blocked with blood-clots, the serum spouted from the opening in a steady stream, carrying with it numbers of small clots. After the flow of serum had stopped, a shorter tube was introduced and fresh dressings applied. 4 P.M: Pulse 104; temperature 98°. Patient is much easier, serum flowing freely. The nurse had drawn four ounces of urine, of a more natural appearance.

30th.—Noon: Pulse 100; temperature 98°: Patient is doing well; feels a desire for food. Bandages, pad, and bed soaked with serum. Every alternate suture was removed, and strips of adhesive plaster applied in their places. Raw eggs were ordered to be given in the beef essence, and some toasted bread allowed. Lithia water discontinued.

31st.—2 P.M.: Pulse 96; temperature 98·1°. During the last forty-eight hours the patient has passed, without the use of the catheter, nine ounces and a half of urine, natural in colour.

April 1st.—10 A.M.: Pulse 96; temperature 99·6°. The patient says she feels quite well. The remaining sutures were removed. Union was perfect. The abdominal wall was firmly supported by wide strips of adhesive plaster. The drainage-tube was removed, the ligatures being sufficient to keep the opening patent.

From this time onward the patient progressed towards recovery without one bad symptom. Occasionally there would be a slight elevation of temperature and an increase in the heart's action, but at no time sufficient to cause anxiety or necessitate treatment. The bowels were not moved until the sixteenth day, and then under the combined action of castor oil internally and repeated injections of tepid water. One month from the day of the operation she returned home. The abdominal opening was still patent and the ligatures firm. In accordance with the suggestion of Sir Spencer Wells, gentle continuous traction was kept on the ligatures by means of a rubber ring, to one side of which the ligatures were attached and the other side made fast to the abdominal wall by strips of adhesive plaster. At the end of eleven weeks they showed no signs of yielding. The continual traction was making the part sore, so I determined to cut them off. I drew them out as far as I could without using too much violence, and pressing the abdominal wall inwards cut them off as short as possible. Undoubtedly the attached portions of the ligatures were encysted. In a few days the opening closed and the patient needed no further treatment.

Throughout the treatment of this case the strictest antiseptic precautions were observed. Neither of the gentlemen who assisted me or the nurse had attended a case of fever or been in contact with any contagious disease for two weeks. Instruments, sponges, towels, and everything used were rendered thoroughly aseptic, and no one but Dr. Bull, myself, and the nurse were permitted to enter the room for ten days after the operation. One might naturally have expected that after so much violence had been done to the peritoneum some inflammation would have followed. There were twenty-three ligatures cut off short and left in the peritoneal cavity, and the stout ligatures around the pedicle, and eighteen ligatures cut off short and left embedded in the abdominal wall. The escape of so much cystic fluid into the abdominal cavity increased the risk, for, however carefully the cavity might be sponged, some portion would surely remain; but during the whole progress of the case the highest point of temperature reached was 100·2°, and the pulse never exceeded 116. A large amount of carbolic acid was necessarily absorbed during the operation; it undoubtedly caused some renal congestion and partial arrest for some days of the renal secretion; but, on the whole, it did much more good than harm, for I am firmly convinced that had not the strictest Listerism been observed in the treatment of this case, I should have lost my patient.

Rome.

CASE OF STARVATION AND SUSPENDED ANIMATION.

BY EDWARD BERDOE, M.R.C.S., L.R.C.P. EDIN.

I WAS called on April 29th, 1885, by an order from the relieving officer of my district, to see a man named Samuel B——, aged seventy-four, at the almshouses of the Parmiter Charity, Bethnal-green. I found him lying on the floor insensible and dying. His wife sat near him, and on being questioned admitted that he had been lying in the same position for six days without food, drink, or any attention whatever. It was only by information from a neighbour that the parish authorities got to know of it. On raising him to place him on the bed, part of the flesh of his face adhered to the floor and was torn off. The exact form of the patient was marked on the floor by the exudation from the skin. He was in a most filthy state, and though unable to swallow even liquids, lived about fourteen hours after my first visit. By the coroner's order I made a post-mortem examination. The body was fearfully emaciated, and all the parts that had been in contact with the floor were gangrenous. The organs presented the usual appearances of death from starvation, but the medical interest of the case was found in the condition of the heart. This was enormously hypertrophied and dilated; all the vessels were atheromatous, and there was a large aneurysm of the arch of the aorta. The cardiac condition seemed to satisfactorily clear up some of the difficulties of the case. From the evidence at the inquest it is probable that the wife's statement was correct, that he had fallen down "in a fainting fit" six days previous to my visit, and had not moved or spoken since. The heart presumably beat with just sufficient force to keep the respiratory organs going; this was, of course, favoured by the recumbent position. The case is interesting from a medico-legal point of view, as showing how long a person may live in a state of syncope.

Victoria-park-gate, E.

A NEW SPLINT FOR THE TREATMENT OF COMPOUND INJURIES AT OR ABOUT THE ELBOW-JOINT.

BY ROBERT JONES, M.R.C.S.,

[illegible] ASSISTANT-SURGEON, STANLEY HOSPITAL, LIVERPOOL.

I HAVE found the annexed figured splints very useful among the out-patients of the Stanley Hospital. One form (Figs. 1 and 2) is composed of two very flexible sheet-iron [illegible] covered with felt, and connected by means of a [illegible] rod, so twisted as to extend beyond the elbow. It thus gives ample freedom for easy change of dressings, without interfering with the immobility of the joint. This is of great advantage where perfect rest and free drainage are required. For comfort's sake the forearm support is extended beyond the wrist—a detail which should on no account be neglected. The connecting bar must be sufficiently strong to admit of no movement at the elbow. Where the wound is unusually large and extends up the arm, I use a modified splint (Figs. 3 and 4), the flexible sheet-iron support being substituted by small wings, which are quite easily bent and can be moulded to the arm without any trouble. The splint is made at any angle which the surgeon, regardful of the possibility of ankylosis, may suggest. This will vary according to the patient's vocation. Generally speaking, a right angle gives the most useful result.

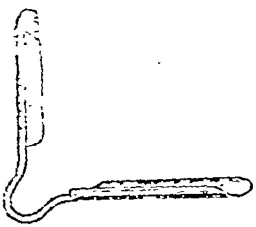

FIG 1

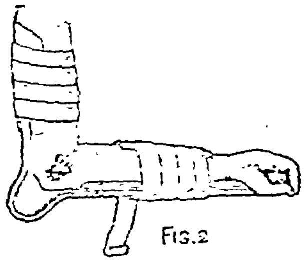

FIG. 2

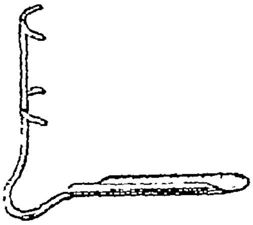

FIG. 3.

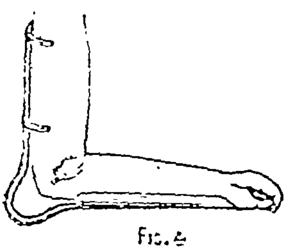

FIG. 4

The splints may be procured at a moderate cost from Messrs. Krohne and Sesemann, London; and from Mr. J. Critchley, Upper Pitt-street, Liverpool.

KING'S COLLEGE HOSPITAL.

A CASE OF EMBOLISM OF THE RIGHT MIDDLE CEREBRAL ARTERY SIMULTANEOUSLY WITH EMBOLISM OF THE RIGHT BRACHIAL: GANGRENE OF THE RIGHT THUMB AND LITTLE FINGER: RECOVERY.

(Under the care of Dr. JOHNSON.)

IT is rare to have embolism of a cerebral vessel and simultaneous embolism of one of the large systemic arteries. The most common source of such embolism is the detachment of granulations from one of the valves on the left side of the heart. This condition of the valves is usually accompanied by a murmur or other indication of the disease, but it is possible to have disease sufficient to produce embolism of more than one vessel without any murmur. Under such circumstances, until a post-mortem examination has been made, such source cannot be decidedly negatived.

For the following notes we are indebted to Mr. T. Sydney Short, medical registrar.

E. W——, aged thirty-nine years, was brought in by his wife, and carried on an ambulance stretcher. He could answer questions, but was incoherent and dazed. His wife said that on the night of March 11th, seventeen days before his admission, which took place on March 28th, he had a fit when apparently asleep, and she found him out of bed and trying to get into bed again. He was completely dazed, and could only just understand what was said to him. She noticed that he had lost the use of his left arm, and that the face was drawn to the right side; and on attempting to feel the pulse could not obtain any beat on the right side at the wrist, but easily felt it on the left side. The forearm and hand were quite cold on the right side, and she also noticed that as they became warmer the end of the little finger and the thumb became black. The paralysis of the left leg came on more gradually, and was complete in a few days. For a day or two after the seizure he had some incontinence of urine, which then passed off. As far as she could say, the sensation of the left side was lost from the first. His memory for all events just before and at the time of the attack was very dim, and although his speech was thick there was no aphasia.

The patient was a healthy-looking and well-made man, with perfectly white hair, which, it was stated, had turned so when he was nineteen years of age; this and a large black beard made him look much older than thirty-nine years. It appeared that from the early part of the year he had been overworked as a clerk, and, besides being very anxious about his work, had been doing some hours overtime. One day he had fainted, for the first time in his life, from sheer fatigue. His family history was good. His parents were both alive, and his mother was getting about fairly well, in spite of a paralytic stroke when sixty years old. He himself had a good history. He had had scarlatina eighteen years ago, but never any rheumatism, and never suffered from anything except from an occasional severe headache when especially worried.

On admission, he had complete paralysis of the left arm and leg, with partial left facial paralysis; on the same side there was total loss of sensation to touch, but he could feel pain as such, not, however, being able to localise it at all. The whole of the paralysed side was bathed in perspiration. At about the junction of the upper with the middle third of the right upper arm a soft plug could be distinctly felt in the brachial artery; there was a pulse above this point, but none below. The greater part of the thumb and the end of the little finger were black and shrunken, and the line of demarcation had commenced in both. There was no evidence of past or present cardiac mischief. The urine was at first passed unconsciously, was ammoniacal, but contained no albumen. Arteries not rigid nor thickened. During the first week his temperature was rather above the normal. He soon regained command over his bladder and moved his left leg slightly. The right hand caused him a great deal of pain, and was relieved by opium fomentations. It was found he could not detect the difference between hot and cold substances, unless they caused pain. For about a month he was sleepy and dull. The progress of the case was briefly as follows:—During April and May he steadily improved, his mind became clearer, and the movement of the left leg increased. On May 7th he was seen by Sir Joseph Lister, and the gangrenous parts were dressed with salicylic wool and bathed daily with a carbolic acid lotion from that day. Rigidity in the paralysed limbs gradually showed itself, and tendency to ankle-clonus was seen during June, and became well marked in July. The sensation of the face improved rapidly, but that of the limbs was absent for touch at this time. On Sept. 12th, and again on Nov. 14th, he had an epileptiform fit; the spasms were most marked on the right side, but commenced on the left, and he was reported to have moved his head towards the right side. The rigidity in the meantime was gradually increasing, and a wrist-clonus was developing on the left side. During January of 1885 he had two more fits, both beginning with left-sided twitchings. The second one was preceded by much headache, and was the last fit he had in the hospital. At the end of January he could not stand on account of his left leg giving way at the knee and ankle; none of the muscles had wasted. The left knee-jerk was only slightly in excess of the right, and the attempt brought on convulsive movements of the leg. Ankle- and wrist-clonus and elbow-jerk were easily obtainable. No abnormal sensations anywhere. Sensation to touch still much impaired in the left limbs, especially in the foot and hand, and improving in passing upwards along the limb from these parts, enabling him to appreciate the difference between heat and cold, which he was unable to do in the hand and foot. He could tell the difference between a knife point and pencil anywhere. The sensation over the left side was nearly normal, being slightly duller than the other. The rigidity is worse after any movement of the limbs, but he thinks himself it is much less. The gangrenous part of the thumb was removed by Sir Joseph Lister on Aug. 15th, and on Oct. 30th the end of the little finger was removed. Both places healed up perfectly, leaving him with a small piece, about half an inch, of metacarpal bone of the thumb projecting, with fair movement; he had an artificial thumb fitted to this.

The patient was discharged on May 1st, 1885; and on June 3rd he wrote the following account of himself with the help of the artificial thumb. He is still unable to stand and thinks there is no increase in the power of the left arm and leg, but that the stiffness in both limbs has decreased. He has had no more fits, but could send no information about the pulse on the right side.

Remarks by Dr. Johnson.—The chief points of interest in this case are the simultaneous occurrence of the left hemiplegia and the embolus in the right brachial artery, making the diagnosis of hemiplegia from embolism almost certain. At the same time there was no clue as to the origin of the embolus, and the point whence it had originally started could not even be guessed at, since the heart was normal as far as could be ascertained.

KENSINGTON INFIRMARY.

A CASE OF OVARIOTOMY; RECOVERY; REMARKS.

(Under the care of Mr. H. P. Potter, Medical Superintendent.)

The patient was a single woman, aged fifty; the catamenia were regular; the duration of the swelling two years. This was situated to the right of the umbilicus; it was globular, smooth, and fluctuating with distinct thrill, measuring five inches in diameter. Potin's aspirator evacuated nearly three pints of clear, limpid albuminous fluid, sp. gr. 1010. This was done eight weeks before the operation. On March 27th, as the fluid had re-collected and the cyst appeared tense, ether was given and an incision three inches long was made immediately below the umbilicus and the cyst exposed. This was found to have many adhesions to the surrounding parts—viz., to the abdominal wall, intestine, and mesentery. All these were torn away, excepting two firm adherent cords which required ligature. The bleeding was so slight that no vessel was tied or twisted. Limpid, dark-coloured fluid was drawn off; a small quantity escaped into the peritoneal cavity. The pedicle was secured with a double stout silk ligature and the collapsed cyst withdrawn from the abdomen. It was unilocular and connected with the right parovarium. Four deep silk sutures were introduced from within outwards, and five superficial catgut stitches joined the edges of the incision, which was covered with antiseptic gauze. Drs. Travers and Atkinson assisted at the operation. Ice-water was alone given for twenty-four hours. The patient had a little vomiting (due to the ether). The temperature on one occasion rose to 99·3°F., with this exception it was normal throughout, and the progress during convalescence was undisturbed. The patient left her bed on the fourteenth day, and gradually regained strength until April 21st, when she was certified for a convalescent home.

Remarks by Mr. Potter.—The importance of rest following capital operations is fully recognised. And in no operation are rest and position more necessary than in ovariotomy. Although this case is by no means peculiar, the special feature I wish to point out shows and tends to prove that in some complicated cases, at any rate, absolute and continuous rest in the horizontal dorsal position and the prohibition of movement, however slight, favours early cicatrisation, and counteracts peritonitis and other serious sequelæ. Mortality after ovariotomy is influenced by the severity of local conditions, the state of the kidneys and other viscera, the health, disposition, and temperament of the patient, the care with which she is prepared, the after-treatment, and nursing. These points are doubtless more worthy of consideration than age, size of tumour, mechanical effects of the swelling, variety of the dressing, and the presence or otherwise of strict antiseptic precautions. In conclusion, I venture to think the instrument usually employed for tapping these cysts is too large, especially in cases where the contained fluid is known to be limpid; it is apt to make a rent in the cyst-wall through which fluid may escape by the side of the cannula. It is found in practice that the abdomen can invariably be emptied in ascites with the pocket-case trocar and cannula. If some material could be found to adhere to the cyst so that the fluid may be carried away clear of the abdomen during the process of tapping, similar to the impervious apron which is commonly applied in these operations to the skin of the abdomen, I apprehend that by the prevention of the escape of fluid into the abdominal cavity, we should obviate a risk against which we have at present no infallible remedy.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

CASES OF STRICTURE OF THE URETHRA, WITH COMPLICATIONS; REMARKS.

(Under the care of Mr. PAUL.)

THE cases of stricture of the urethra which we publish are of interest, each of them being complicated and requiring special treatment. Wheelhouse's operation, which was performed in one case, was described by him in 1876; but, as Mr. Paul observes, it is not necessary to use the special instruments then brought forward, success being equally obtained with instruments which are in almost daily use.

CASE 1. *Old Stricture; Perineal Abscess; Urinary Fistula, becoming epitheliomatous.*—Josiah C——, aged fifty-four, a seaman, had suffered many years from stricture (he says thirty), but had never been treated for it. He sought admission on account of a perineal abscess. Under ether the abscess was opened, the stricture divided, and a full-sized gum-elastic catheter passed and tied in. On the third day the catheter came out and was not reintroduced, a Lister's bougie being passed daily instead. At the end of two months he was discharged almost well, but warned to attend as an out-patient for some time to get the bougie passed, as the stricture showed a strong tendency to contract again. He was an extremely nervous man, and once out of the hospital had not the pluck to continue treatment, the result being that in the course of a few months he had another urinary abscess worse than the first. He kept away from the hospital until he found that he was getting in a very bad way, when he returned in the following condition: the scrotum and the whole of the perineum and neighbouring parts were brawny and tender. Just behind the former was a ragged, foul-smelling sore, eating deeply into the perineum along the tract of the original fistula. Its edges were hard and epitheliomatous in appearance, and upon scraping the surface of the sore the characteristic "nest cells" were found in abundance. The disease was too far advanced to permit of any attempt at removal, and came to a fatal end in about three months, the actual cause of death being cellulitis. At the post-mortem the growth was found to be limited to the perineum and neighbouring glands, involving all the parts down to the arch of the pubis and spreading freely into the scrotum. The prostate and bladder were quite free.

Remarks by Mr. PAUL.—I believe that this is a very rare sequence to a urinary fistula, and it is very unfortunate that there were no means by which the exact origin of the epithelioma could be determined. It is difficult to distinguish microscopically epithelioma of the bladder from epithelioma of the skin, and the same holds good with the urethra. The whole case lasted only ten months. When first seen, the skin of the perineum was unbroken, it was quite free from growth two months later, and then, at the end of another five months, was the site of a large and very deep epithelioma. Under these circumstances, I inclined to the opinion that the growth commenced in the urethra, and was excited by the prolonged stricture; just as simple syphilitic stricture of the œsophagus sometimes ends in epithelioma of that structure.

CASE 2. *Stricture; Cystitis; Wheelhouse's Operation.*—James P——, aged thirty-four, had gonorrhœa when a lad and had suffered from stricture for the last sixteen years. He had often been under treatment at the various hospitals in the town, but had never had anything larger than a No. 6 or 7 passed except on one occasion when Mr. Harrison ruptured the stricture with Holt's dilator. After this he learnt to pass a catheter for himself, but had only used the smaller [illegible], and came to the hospital, as he could get nothing more in, and was scarcely able to pass his urine. On admission he was in good general health. There was a cartilaginous stricture in the perineum which would just admit the smallest soft bougie. The urine was foul and contained a quantity of mucus. At the end of three days no dilatation had been effected with catheterism, and the bladder symptoms were becoming more urgent; Wheelhouse's operation was therefore performed at once. The patient was placed in the lithotomy position, and a long silver probe passed down to the stricture. An incision was then made on to the end of the probe, which was pushed out of the wound and bent into a hook. The sides of the urethra were held open with artery forceps, a grooved probe insinuated through the stricture, which was divided, and the probe passed on into the bladder. It was now quite easy to pass a full-sized Lister's bougie from the penis to the bladder; so the patient was sent back to bed without having a catheter tied in. At the end of a week the urine was quite clear and all irritation of the bladder had ceased; so, instead of the daily passage of a bougie, a large gum-elastic catheter was tied in. While the catheter was kept in all the urine came by it, and the wound healed rapidly. It was removed in ten days, and the patient taught to pass a No. 12 Lister's bougie, and discharged a few days later. Altogether he was in the hospital only from Jan. 12th to Feb. 7th.

Remarks by Mr. PAUL.—I send this straightforward case for publication because I have so often felt the advantage of an early operation of this nature in stricture cases, and because I often notice that my surgical friends, while they laud the method advocated by Mr. Wheelhouse very rarely seem to adopt it. In the hands of specialists internal operations upon the urethra are much in vogue; at present I have never either split or divided internally a stricture, except in the penis, preferring in all cases where an operation is necessary to do perineal section. I think it is a pity that Mr. Wheelhouse recommends special instruments for his operation, as it is quite as easy to do it with those always at hand; and, with all due deference to his opinion, I do not find his sound and gorget of any material assistance, while their absence might influence some to attempt a different method of giving the necessary relief to the patient. In this case a catheter was not tied in at once on account of the cystitis; and at the conclusion of the treatment I adopted my usual practice of teaching the patient to pass a large metal sound for himself. It is the only permanent cure for most strictures, though but few, of the hospital class at any rate, are wise enough to adopt it.

CASE 3. *Stricture; Retention; False Passage; Relieved by Puncture per Rectum.*—James F——, aged twenty-seven, had gonorrhœa some years ago, but passed urine in a full stream until about twelve months back, when he had his first attack of retention of urine after a drinking bout. Since then, under similar circumstances, he has had three or four more attacks of retention, and at the same time the stream of urine has been steadily diminishing in volume during the intervals. On Feb. 2nd he was drinking, and on the morning of the 3rd was again attacked with sudden and complete retention. Relief had been attempted by catheter, and he bled profusely, but no urine was drawn off. He was admitted with the bladder moderately distended in the afternoon, and was in great pain. A metal catheter was passed into the urethra, but opposite the bulb left it for a false passage, and on withdrawing the instrument he at once strained away about an ounce of blood. Under these circumstances a morphia injection was given, and he was ordered to have a hot bath shortly, to be followed by hot fomentations to the abdomen, and further morphia if necessary. In the evening, though the treatment had given some relief, not a drop of urine had been passed, and it was therefore deemed advisable to puncture per rectum. The next day he was perfectly comfortable, and the urine was draining freely through the cannula.

On the 5th, after plugging the tube, he was able to pass urine by the penis, and it was consequently withdrawn.

6th.—Had a rigor, with nausea, headache, and diarrhœa. Temperature 104°. Ordered five grains of quinine every four hours.

7th.—Temperature fell below 100°, and became normal in a few days. The quinine was stopped on the 9th.

12th.—Soft bougies passed. No. 3 was the first to be gripped by the stricture, which was dilated to No. 6.

24th.—The patient was discharged with the stricture fully dilated.

Remarks by Mr. PAUL.—In a case of this kind, I think the choice lay simply between aspiration of the bladder and puncture per rectum. I chose the latter entirely on account of the false passage. In acute retention, when, though the urethra is uninjured, no instrument can be passed, aspiration is called for, and will almost invariably not have to be repeated, since the relief afforded by it, together with other suitable treatment, will permit the swelling and spasm of the urethra to subside, and in the course of twelve hours either the patient will have passed urine naturally, or it will be possible to introduce a catheter. But when a false passage is present, and it is extremely unadvisable to interfere with the urethra for at least a week or ten days, the better plan is certainly to adopt puncture per rectum, and retain the cannula *in situ* until the power to micturate has returned. The pyrexial attack on the 6th I believe to have been due to some urine filtering into the false passage and permitting septic absorption, as no instrument was passed until the 12th, and no trouble of any kind appeared in connexion with the rectal puncture. I am a strong advocate for early operation in all cases of obstruction to the outflow of urine, when that obstruction cannot be easily overcome by catheterism. We ought to remember that the kidneys are the only part of the urinary tract of vital importance, and, sooner than permit their structure to be damaged, a clean incision should always be made into the urethra or bladder, as the case may require. Sadly too often, while we are wasting time over a cartilagenous stricture with small bougies, pyelitis is grafted on to cystitis, and suppurative nephritis may develop at any moment, and show too late the danger of delay.

Medical Societies.

THE ABERNETHIAN SOCIETY.

SIR JAMES PAGET ON ST. BARTHOLOMEW'S HOSPITAL AND SCHOOL.

A SPECIAL meeting of the above Society took place on Monday, June 8th, Mr. W. T. H. Spicer, President, in the chair.

Sir JAMES PAGET, Bart., gave an address on "St. Bartholomew's Hospital and School fifty years ago." A large number of the members were present, together with about 120 of the nursing staff, who were invited as guests. Sir James Paget began by describing first the exterior of the hospital, saying how much more classical it was in appearance than now, and how all the four blocks which surround the square were then connected together by arches or gateways, which led into the neighbouring streets. A great improvement had taken place since then in that the square was now much quieter, for then it was almost as noisy inside as outside, where a cattle fair was held every week. In fact, it was a public thoroughfare. In some respects it was more rural, for attached to the vicar's house was a garden in which a mulberry tree flourished, and of which the vicar was very proud. Dr. Hughes was accustomed to say that he had heard the nightingale singing there. He (Sir James Paget) then went on to speak about the school buildings, and showed what great alterations had taken place lately, and how entirely changed was the whole locality. The operating theatre was what is now called Sitwell Ward. In the neighbourhood was a students' club situated over a baker's shop; here the students were accustomed to congregate and spend a good deal of their time in playing cards. He next spoke of the teaching, and mentioned how the majority of students had been apprenticed to general practitioners for three or four years before coming up to the hospital. Here they spent about eighteen months, which was quite sufficient time for them to obtain a very fair knowledge of medicine, considering the time they had already been at it. There was then only one examination at the College of Surgeons for the diploma. This consisted of about twenty-five minutes' *vivâ voce* before a number of the Fellows, all of whom sat at the same table. The teaching was entirely by lectures, the most eloquent of which were those given by Sir William Lawrence. Mr. Stanley used to lecture on Anatomy. This lecturer was remarkable not so much for the minute details as for the comic manner in which he delivered them, and for the curious so-called "tips" which he gave to the students to help them to remember their work. Dr. Hume, senior physician, lectured on Chemistry, which included Light, Heat, and Electricity; and, in addition, on Botany, Medicine, and Materia Medica: seven different subjects. He mentioned this in order to show how impossible it would be, in the present advanced state of these sciences, for any physician to teach properly so many subjects. There was very little clinical teaching; in fact, at this time the school was in a rapid state of decay as far as the teaching was concerned. With regard to the hospital staff, Sir James Paget said that the quality was excellent, but that the number was much smaller than it is now. There were three physicians and three surgeons; each had an assistant. In addition to this there was an apothecary. The junior staff consisted of one house-surgeon and five dressers to each surgeon. The house-surgeons lived together over King Henry VIII.'s gateway, facing Smithfield Market. The dressers were appointed from six to twelve months. There were no special departments, such as the ophthalmic, aural, and orthopædic departments. The great treatment at that time was bleeding, and he remarked that it would be difficult to say in what cases bleeding was not used. To everything which was acute bleeding was applied. It was used as a means of producing muscular relaxation, and was also used as an anæsthetic. Twelve to thirteen ounces of blood were frequently extracted from a man before a dislocation was reduced. Yet, notwithstanding, it was very rare for any mischief to arise from this practice. The large majority of patients recovered from the loss of blood, and in certain diseases he had no doubt a number of people benefited by it. Mercury and sarsaparilla were the only remedies used for syphilis at that time. Potassium iodide was just being introduced by Dr. Robert Williams, and was only commencing to gain reputation. Sir James Paget then went on to say that he thought diagnosis should be the future study of students to a much more minute extent than it was even now, and they should notice how the personal character of a patient influenced the disease, and also the action of the drug. He next referred to the surgical operations of the day, and remarked that not only was the number smaller, but the method of operating also differed greatly. Swiftness, simplicity, and brilliancy were the chief qualities of a good surgeon. These were essentially necessary, as they might very well understand if they remembered that anæsthetics at this time did not exist. For the same reasons surgical instruments were far less elaborate than now. The patient was placed on a lowering diet, and purgatives were administered for some days before the operation. Organic defects in the kidney, heart, &c., were not looked for, and hygienic treatment was very defective, so that it was not surprising if the mortality of operations was greater than now. The lecturer then referred to the nursing staff, and said that the sisters in those days, as now, were very practical women, but that the nurses were very far inferior, both in their capabilities and their social position, to what they are now. Finally, Sir James Paget made a few remarks on the medical students of fifty years ago, and said they were certainly not so refined, perhaps, as nowadays; but at the same time we should remember that society in general was also less refined. On the whole they were a hard-working set of men. In conclusion, he thanked the Society for having honoured him by asking him to address them, and said what great pleasure it had given him to lecture to a body of students again.—Dr. MATTHEWS DUNCAN then in a few words proposed a vote of thanks to Sir James Paget for his interesting lecture, remarking at the same time that he thought it would be very satisfactory if the Society were to ask Sir George Burrows to relate to them the curious manner in which patients were examined in those days.—Dr. NORMAN MOORE seconded the proposal in a few appropriate words, which was carried unanimously amidst much applause.

Reviews and Notices of Books.

Selected Monographs. 1. Albuminuria in Health and Disease, by Dr. H. SENATOR. 2. Some Considerations on the Nature and Pathology of Typhus and Typhoid Fever, by the late ALEX. P. STEWART, M.D. 3. Movable Kidney in Women, by Dr. LEOPOLD LANDAU. London: The New Sydenham Society. 1884.

THIS volume is composed of three essays, differing as widely in their style and character as they do in the subjects of which they treat; but they were all worthy of reproduction, as they are of careful perusal. Dr. Senator's monograph on Albuminuria may be taken as the latest utterance of science upon this obscure and difficult subject, to the elucidation of which the author has contributed so much. His views are based upon a theory of urinary secretion (which is more explicitly dealt with in a lecture appended to the essay) that differs to some extent from any that have hitherto been adopted. Thus, he regards the physiological process as made up of two components—a filtration or transudation by the agency of the glomerular tufts, and a true secretion by means of the glandular epithelium of the convoluted tubes. In some respects this is a reversion to the teaching of Bowman; and it differs from that of Heidenhain, who considered that secretion occurs through the glomerular epithelium as well as the tubular. Senator, however, believes that in the glomeruli we have to do merely with a transudation obeying the ordinary laws of that mechanical process, modified it may be by the special peculiarity of the vascular arrangement. He does not therefore hold that only the urinary water escapes by the tufts, but that there is an exudation of all blood constituents. A certain amount of serum-albumen and globulin must therefore transude, limited probably by the epithelial lining of the capsules. Sufficient, however, escapes to justify the belief in "physiological albuminuria," varying in degree according to circumstances of diet, exercise, and the like. The addition of more water and of the peculiar secretory products as the urine passes down the tubule reduces the percentage of normal albumen to a minimum, and this may still further be diminished by absorption. He quite discards the notion that any considerable amount of albumen normally transudes to be taken up by the epithelial cells, as was once maintained. The interesting subject of peptonuria and of propeptonuria, where the albumen is non-coagulable by heat, is alluded to, these conditions being attributed to the presence of such modifications of albumen in the blood under certain conditions. The essay deals in turn with the influence of alterations in blood pressure, in the renal epithelium, and in the condition of the blood, in inducing albuminuria. As to the first point, it is shown that the various forms of congestion produce albuminuria, but in various ways. Thus, temporary ligature of the renal vein causes exudation of albumen chiefly into the medullary tubules; cutting off the arterial supply is followed at first by this exudation into the Malpighian capsules, and later into the tubules; occlusion of the ureter leads to great dilatation of the tubules and of the interstitial lymphatic spaces, which become filled with albumen before this appears in the capsules. In degeneration of the renal epithelium albuminuria is to be attributed in part to the débris of the epithelial cells, and in part to increased transudation from the blood. Lastly, morbid conditions of the blood may induce albuminuria by increasing the transudation capacity of the glomerular tufts, while abnormal albuminous substances in the blood probably pass out more readily than the normal. In febrile and inflammatory states the condition becomes more complex, for in the latter there is the additional factor of inflammatory exudation, and especially the involvment of the glomeruli in this process. Besides the lecture on urinary secretion, there is also appended an essay on the Hygienic Treatment of Albuminuria, in which milk diet, baths, the avoidance of chills and of muscular exertion, and a sojourn in dry warm climates, form the chief recommendations. The translation is faithfully rendered by Dr. T. P. Smith, and the monograph is one which requires to be carefully studied, for it is full of closely reasoned argument.

The reproduction of the late Dr. Stewart's memoir, which was read before a Paris Medical Society in 1840, serves to remind us that a great share was taken by this physician in establishing the distinction between the two great continued fevers of this country. The essay shows how clearly Dr. Stewart had grasped the notion of the two distinct types of fever, which he had ample opportunity of observing at Glasgow; and yet, influenced doubtless by the *force majeure* of British opinion, he hesitated to do more than suggest that a case was made out for further inquiry. For Dr. Stewart's sake, it is to be regretted that he did not possess the energy to follow up his researches; but then perhaps we might not have had the masterly exposition of Jenner nine years later, which clinched the question beyond dispute. It is right, however, to bear Stewart's work in mind, for it was much in advance of the orthodox teaching of this country, and it shows that he possessed remarkable clinical acumen as well as independence of thought. The essay has been edited by Dr. Cayley, who appends a memoir of the author.

The essay of Dr. Leopold Landau on Movable Kidney in Women fills a gap in medical literature. It deals with the subject in the most thorough manner, but space forbids our attempting any analysis of the work, for the translation of which we are indebted to Dr. Champneys. It may be noted, however, that a considerable part in the production of hydronephrosis is assigned by the author to this interesting condition.

Operative Surgery in the Calcutta Medical College Hospital: Statistics, Cases, and Comments. By KENNETH MCLEOD, A.M., M.D., F.R.C.S., Fellow of the University of Calcutta; Surgeon-Major, Indian Medical Service; Professor of Surgery, Calcutta Medical College; and First Surgeon, College Hospital. London: J. and A. Churchill. 1885.

WE have read this book with great interest and pleasure. Dr. McLeod has tabulated all the operations performed by him in the Calcutta Medical College Hospital during his five years' term of office as first surgeon in charge. But he has done far more than tabulate his cases, for, in addition to a short description of each case, he has contributed comments upon each group or class of operations. In this way the dry details of statistics have been clothed with living interest, and the reader is made to realise in no imperfect manner the conditions of surgical practice in Calcutta, and the actual scientific and practical outcome of the entire operative work of five successive years. In discussing the mortality after operations in general, Dr. McLeod lays stress upon the importance of septic poisoning, and shows that patients in this hospital are specially prone to the ravages of all septic diseases. Suppuration occurs in the natives with great rapidity and frequency, and their lack of stamina—at any rate in Calcutta—leaves them an easy prey to exhaustion and blood-poisoning. The state of the hospital was formerly very bad; and, as shown by Sir Joseph Fayrer in his "Clinical Surgery" and "Clinical and Pathological Observations in India," erysipelas and osteo-myelitis used to be endemic in the wards. Much has been done to improve this state of things, and the success of these efforts was quite observable. But Dr. McLeod shows conclusively that the introduction of a careful aseptic treatment of wounds has been a far more powerful weapon against the evil results of operations and wounds. He confesses himself to be—and not without good reason—a warm admirer of Sir Joseph Lister's plan of wound treatment; and it is noteworthy that he found himself unable to carry out the treatment with full success until he had carefully studied it as practised by Sir Joseph Lister himself. This is but another proof that the reported failures of many surgeons who profess to practise antiseptic surgery are to a large extent due to their failure to carry it out efficiently. Although fully alive to the predisposition among his patients to the development of septic diseases, Dr. McLeod states: "I have never seen septic disease of any sort arise in a patient whose wound was in an aseptic condition; and, on the other hand, in those cases in which I have had the misfortune to witness the development of constitutional septic disturbance, this has always been preceded or accompanied by manifest signs of local putridity." Full as the book is of interesting matter in every part, most readers will be specially interested in the chapters devoted to the treatment of elephantiasis scroti and the radical cure of hernia. In each operation Dr. McLeod has had considerable experience. He is a strong advocate for the direct operation for hernia, including ligature of the neck of the sac, removal of its fundus, and suture of the fibro-muscular walls of the inguinal canal. He gives in full detail his method of operating, which is the best we are acquainted with. The almost total absence of strumous diseases of bones and joints and allied affections, and the frequent occurrence of tetanus, are striking to an English surgeon. In view of the attention which is just now being given to the alleged increased frequency of malignant disease in England, it is important to note that Dr. McLeod shows that this disease is very common among the native population in India. This is no new fact, but the statistics before us fully demonstrate it. Surgical scarlet fever is an affection which has recently excited a good deal of attention, and at the close of last year an important discussion upon it occurred at the Medical Society of London. It was then shown—we think conclusively—that there are cases which may truly be called surgical scarlet fever. But more than one speaker referred to cases of erythema coming on after operations which could hardly be included under this category. We notice that Dr. McLeod incidentally affords us some interesting evidence on this point. He states that he has observed "several instances" of "surgical scarlatina," but adds, "as scarlet fever is an extremely rare disease in India, it is quite certain that surgical erythema is a distinct malady from scarlatina." We have no space to refer to many other points of interest dealt with more or less fully and directly by the author, but we must add that while writing of the results of his own work he has rendered his book remarkably impersonal, and the reader is but rarely reminded of a fact which too many authors never fail to obtrude.

New Inventions.

THE HOLLOW EYE SPECULUM AND DOUCHE FOR THE TREATMENT OF GONORRHŒAL OPHTHALMIA.

THE two chief obstacles which are met with in the treatment of gonorrhœal ophthalmia are—the rapidity with which the discharge re-forms after its removal, and the difficulty of applying astringent or antiseptic solutions to the inflamed conjunctivæ on account of the swelling of the lids. So great is this difficulty that the external canthus has often been divided to remedy it, and the late Mr. Critchett even divided the upper lid through its centre and stitched its halves apart. The hollow eye speculum and douche is an instrument which Messrs. Weiss and Sons of the Strand have made for me to overcome these two difficulties. It consists of an ordinary spring speculum, the two limbs of which are hollow and prolonged separately for about a quarter of an inch beyond the spring; these are each connected by means of indiarubber tubing to the two arms of a Y-shaped piece of metal tubing; the foot of the Y-shaped *piece is joined by another piece of tubing to the tap of an* irrigator. The outer borders of the portion of the limbs of the speculum which pass beneath the lids of the patient are each perforated by four holes, the lower part fitting into the upper so as to facilitate its introduction between the inflamed lids. The patient lies on his back on a couch; the speculum, having been connected to the irrigator which hangs above the patient's head on the wall, is introduced, and the tap turned; the fluid then circulates from the irrigator down the tubing to the Y-shaped piece, through its two arms to the limbs of the speculum, and out at the holes into the conjunctival sacs; the patient holds a kidney-shaped tray close to the side of his head to catch the waste fluid. In this way the accumulation of the discharge can be prevented and antiseptic and astringent solutions efficiently applied to the whole of the conjunctival surface. Mr. Edgar Brown has published a description of an instrument of his invention which consisted of a hollow elevator. The advantages I would claim *for the hollow speculum are:—First,* it does not require to be held in; once fixed, the patient can manage it himself. Secondly, it irrigates both conjunctival sacs at the same time. Thirdly, it can be used as a speculum and the condition of the cornea investigated, and any medicament that is necessary applied to it. E. TREACHER COLLINS.

Royal London Ophthalmic Hospital, Moorfields, June 9th, 1885.

RUSSIAN EXPERIENCE IN THE TREATMENT OF VARIOLA.

DR. REIMER, in a paper read before the St. Petersburg Medical Society, summarises his experience of the various methods of treating variola that have been recommended of late years, an experience extending to 1300 cases. These methods are as follows:—

Weidenbaum's ointment (cinereum with soap and glycerine). The pustules developed rapidly, but distressing itching followed, and the course of the fever was not shortened.

Caoutchouc solution.—With children a burning sensation was complained of. *Four of these cases died of septicæmia.*

Nitrate of silver appeared to have no effect on the result, except that the scars were unusually deep.

Hebra's iodine application.—Great pain was experienced, and the pustules ran together into a large scab, which fell off somewhat quickly; but this had but little influence on the formation of the cicatrix.

Corrosive sublimate was tried in forty-six cases, with careful watching on account of its poisonous properties. A solution of 1 to 500 was employed, a mask being saturated with it and applied four times a day, for ten minutes, to the face. The development of the pustules seemed to be hastened somewhat, but the scars were much the same as when other treatment was adopted.

Schwimmer's carbolic oil paste.—Schwimmer said the patients liked this method, as it reduced the feeling of tension, and that no case of serious suppuration of the face had occurred; also that the drying up generally occurred *on the ninth to the eleventh day, instead of from the thir*teenth to the fifteenth, and always taking place several days earlier on the face than other parts of the body. Reimer found considerable difficulty in employing this treatment with children who could not be got to keep on the mask; he therefore substituted a powder in which carbolic acid was made up with talc, starch, and chalk. He did not find the powdering, which was carefully done four times a day, a very agreeable operation, owing to the repulsive mixture formed with the pustular secretion, or, indeed, very advantageous, as he could not observe that in any of the seventy-seven cases in which it was used the suppuration was perceptibly modified. The same may be said of the forty-eight cases in which he used the paste. Under the micro*scope there was certainly a diminution of* micrococci chains and pus corpuscles. Under the carbolic treatment thirteen children showed symptoms of carbolic poisoning; in three of these life was with difficulty preserved. Nephritis occurred in twenty-six cases, seven of these having hæmaturia.

Under *Burkhard's and Zülzer's xylol treatment*, fifty-two cases were observed, but the formation of the cicatrix was but little modified.

Afterwards, Dr. Reimer tried a number of highly commended methods of treatment, without any satisfactory result. Happening to make use of *salicylic acid* in a case of hæmorrhagic small-pox with the hope of reducing the temperature, he was struck with its remarkable effect upon *the disease, and then remembered* that Schwimmer in 1876, and subsequently Claridge, had recommended salicylic acid. The acid was given in five-grain doses every two hours in fourteen cases with marked effect, the course of the disease being in all cases shortened. Microscopic examination of the blood of patients in the early stage showed that with a single day's treatment the rod-shaped bacteria which had been distinctly visible had completely disappeared.

THE LANCET.

LONDON: SATURDAY, JUNE 20, 1885.

The election of members of the Council of the Royal College of Surgeons of England, which will take place on the 2nd of July next, will be one of the last conducted on the old lines. Not only may the mode of election and the conditions of eligibility of candidates be altered before another year comes round, but it is in the highest degree improbable that after this year any candidate will deliberately stand forth as the acknowledged and accredited champion of the character, constitution, and traditions of an unreformed Council. Reform is in the air, and reformers are in the ascendant. Whether the latter will determine to make their influence prevail this year or not will perhaps depend rather upon sentimental considerations than upon a rigid adherence to political convictions. In some respects the issue is a simple one. Three members of Council are retiring by rotation. Two of these, Messrs. **Erichsen** and **Holmes**, are known to have steadily and consistently endeavoured to effect some amendment in the Council, and to bring this body into harmony with those whom it nominally represents. On the other hand, the third retiring candidate, Mr. **Savory**, is equally well known to have opposed and resisted most of these endeavours. Unfortunately, this gentleman is the only one of the retiring candidates who seeks re-election; so that Mr. **Savory** seeks re-election not only as one who has notoriously voted against the adoption of some of the recommendations of the Association of Fellows to which the Association attaches very great importance, but he comes forward as the representative of those traditions of the Council which many believe to be in the highest degree inimical to the interests not only of the College itself but also of surgical science and art. Elected to an examinership in 1870, Mr. **Savory** continued to hold this coveted post after election into the Council in the year 1877, and resigned it only a few months ago, after having held it for a period of nearly fifteen years, and in spite of an existing resolution of the Council disapproving of anyone holding the office for more than a maximum period of ten years. It is impossible to predict what influence these considerations may have upon the voting next Thursday week. It need, however, occasion no surprise if many Fellows decide that Mr. **Savory**'s great administrative abilities and his experience in the affairs of the College more than compensate for these grave disqualifications. It is a striking testimony to the forbearance and moderation of the Association of Fellows that it has resolved not actively to oppose Mr. **Savory**'s re-election. To expect the Association to promote his election would be to look for a loving-kindness almost more than human.

The contest for the other vacant seats will be unusually keen. The candidates are, in their order as Fellows, Messrs. **Gant**, **Mason**, **Rouse**, **Cowell**, **Macnamara**, and **Pemberton**. Four of these gentlemen have not only been candidates in former years, but they are otherwise known to take an active interest in all matters relating to medical education, ethics, and politics. The two other gentlemen, Messrs. **Mason** and **Rouse**, have not, we believe, hitherto manifested any such interest, and until they do assume a distinct political character it is scarcely likely that they will have a substantial following. The contest, therefore, may be expected to be carried on between Messrs. **Gant**, **Cowell**, **Macnamara**, and **Pemberton**. Considering that the last-named gentleman was only five votes behind a successful candidate last year, his election this year may be deemed almost certain. Mr. **Pemberton** is a provincial surgeon of deservedly high repute, and he has proved on more occasions than one that his political convictions are clear and strong, and, what is more to the purpose, that he has the courage of his convictions; and if the pitiable lapses of some recently elected members of Council are called to mind, moral courage must be welcomed as by no means an insignificant qualification for a seat in the Council. Of the remaining candidates, Mr. **Gant** and Mr. **Macnamara** are both known to be strenuous advocates of educational and collegiate reform. The latter gentleman has quite recently, in the part he has taken in promoting a University improvement scheme, given practical proof of his anxiety to improve medical education in England, and to remove some of the grave disabilities which embarrass metropolitan students. His candidature therefore cannot fail to be acceptable to all who consider that amelioration of medical education and medical status is intimately bound up with the reform of the Council of the College of Surgeons.

◆

The International Sanitary Conference at Rome has suspended its sittings, and will not again meet until the latter part of the year. We may therefore at this stage briefly review its proceedings, and learn something of its views from the decisions at which it has already arrived.

The Conference began its business by appointing in the first instance a Technical Commission of all the medical members to consider and report on those points which required professional knowledge. Our columns have contained accounts of the proceedings of this Commission, which have shown that, although the old belief in quarantine has not yet altogether departed, its end is not far distant. It is, indeed, difficult for countries which have made little or no effort to improve their sanitary condition at once to abandon any method which has about it the semblance of protection. For them the introduction of disease means disaster, and it is only when they have absolutely appreciated the uselessness of quarantine that they will fully consent to seek other means of safety. Nevertheless, the decisions to which the Technical Commission have come show distinctly that opinion is gaining ground in favour of the system of medical inspection which in this country has replaced quarantine. At an early meeting of the Commission quarantine measures by land were voted to be impracticable, and therefore useless; and it was only as regards maritime quarantine that a different view was taken.

Thus it was decided that every vessel passing from the Red Sea into the Mediterranean should be inspected by an officer appointed by an International Commission, and that he should have authority to determine whether the vessel was "suspect" or not, and that it should only pass through the Canal if this point were decided in the negative. If cholera drugs. The medical profession is the indispensable profession of all classes. It will never be found exacting or ungenerous in its dealings with the poor; but it must, for the very poor's sake as well as for its own, claim its rights. The present political discussions on the disfranchisement of electors for receiving medical relief are very important. A sound law on the subject may give an enormous stimulus to independence and self-help. On the other hand, it will be a public misfortune if the exigencies of mere party politics lead public men to make light of improvidence in medical matters.

Annotations.

"Ne quid nimis."

A TEACHING UNIVERSITY FOR LONDON.

ON Monday last another meeting of the delegates from the medical schools and the Executive Committee for promoting the formation of a Teaching University took place at the Society of Arts, and a draft report, which we publish on page 1143, was agreed to. The outline of the plan for a Teaching University, so far as the Medical Faculty is concerned, may therefore be looked upon as complete; but we understand that the Faculties of Art and Science are lagging behind in organisation, whilst the scheme of the Faculty of Laws is altogether in abeyance. If the project as a whole is to survive, it will be necessary for the promoters to lose no time in consolidating the other Faculties. With the ground plan which is suggested in the report for the University, but little fault can be found, and the sequence and relation of its constituent elements seem to be quite right and proper, but we question whether it will be wise, supposing the University ever to be founded, to deprive graduates of all share in framing its regulations and its management. The present report makes no mention whatever of graduates, so that they will be given a degree only. The oldest graduate will have less to say about the proceedings of the University than the youngest teacher, whose degree may have been obtained elsewhere, or who may not have a degree at all. Again, has not too much power been given to the governing body?—for the Boards of Studies are merely to recommend, and there is no security that the governing body will act on such recommendations, and if it does not, the Boards of Studies can do nothing. The proposition for the concentration of the scientific teaching in the medical schools is a very good one, and has frequently been urged by us, but we question very much whether the practical solution of the difficulties involved is within the power even of the Teaching University. The Colleges and medical schools are sure to regard with great jealousy the suggestion to establish chairs in connexion with the new body; for, unless very carefully guarded against, a new teaching body will be added to those already existing, which are now too numerous. But probably these criticisms are premature and of little real importance, for the scheme has a very difficult future yet before it, and we welcome it rather in its bearings on the present University than in view of a possible second university in London. The Special Committee, under the chairmanship of Lord Justice Fry, is summoned for Friday next, to consider the report of its subcommittee, so that the centre of interest has again shifted to Burlington-gardens.

AN EARLDOM FOR MR. GLADSTONE.

WHATEVER may be thought of Mr. Gladstone's foreign policy, there can be but one opinion of his conspicuousness as a public figure and his high qualities as a public man. No State can afford to do otherwise than hold such a man in honour, and it would bode ill for Parliament if it ever ceased to include at least one such man, and to regard him with more reverence than has occasionally of late been awarded to him. The offer of an earldom by Her Majesty is a fit tribute to one of the greatest servants that has served one of the best of Queens. We have often urged Mr. Gladstone's elevation to the peerage. We well know that such a sphere has not greater attractions for him than the House which he has so much adorned, and the fame of which he has so well sustained. But the atmosphere is calmer, and the hours are more reasonable, and—a benevolent motive will weigh more with the illustrious statesman—his acceptance of an earldom would be kind to the Upper House, and supply the material it wants to make it what it must be if it is to remain a veritable House of distinguished men.

ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR ENGLAND.

THE issue of the Registrar-General's 46th Annual Report gives the detailed vital statistics of England and Wales for 1883, supplementary of the briefly summarised statistics of that year published in the Quarterly Return for the fourth quarter of 1883, and in the Annual Abstract presented to Parliament early in 1884. The main features of the statistics of 1883, as well as those of the more recent year 1884, were a continued depression of marriage- and birth-rates, mainly the result of the prevailing commercial depression, and the maintenance of the remarkable reduction in the national death-rate which dates from the year 1876, when the Public Health Acts of 1872 and 1875 may be presumed to have come fully into operation. During the first thirty-three years of civil registration the English death-rate was practically stationary at 22·4 per 1000, whereas in the five years 1876-80 it declined to 20·8, and in the first four years of the current decennium it has further fallen to 19·4. This result in the face of steadily increasing urban aggregation affords the most triumphant reply to the race of sanitary sceptics, if it be not yet extinct. The analysis of causes of death in the Registrar-General's last annual report, however, affords abundant evidence that the "rest and be thankful" stage of the sanitary crusade against preventable death and disease has not yet been reached. In proof of the fact that a remunerative field for further health progress still remains we need only point to figures in the report under notice showing that the recorded death-rate in 1883, in Lancashire and in Monmouthshire, was equal to 22·3 per 1000, while it did not exceed 16·6 either in Oxfordshire or in Berkshire; and, further, that those recorded rates considerably understate the real excess of mortality in Lancashire and Monmouthshire during 1883.

THE BLOOD IN SCURVY.

SEVEN cases of uncomplicated scurvy, three of which proved fatal, were last summer under the care of F. Stazevich in the military hospital at Moscow. The blood examined by Lavdovski's osmic acid solution (1 per cent.) showed irregular red corpuscles of dissimilar magnitude, also more or less atrophied corpuscles adhering together. After recovery this irregularity disappeared. Two cases died of intestinal hæmorrhage, one of hæmorrhagic pleuritis. The blood of these was found at the autopsy to be dark and fluid. In the cardiac cavities and large vessels there were either no coagula or they were of a light colour, and easily torn. In two cases extravasation was found in the pleura, the surface of the heart, and the aortic valves. The spleen was enlarged, light coloured, and easily broken down; the liver enlarged; the cortex of the kidney increased in thickness. The intestinal mucous membrane was soft, swollen, and contained extravasated blood; the solitary glands were only enlarged in one case, and there was likewise ulceration of the colon only in one case; the peritoneal glands were invariably enlarged, and the brain was very anæmic. Under the microscope some of the preparations of the muscles of the buttock showed small extravasations of blood between the fasciculi; the liver cells were enlarged and cloudy, also the epithelium of the urinary passages; the alveoli of the peritoneal glands were much enlarged, and filled with round cells of the size of white blood-corpuscles. The mucous membrane of the small intestine could scarcely be recognised under the microscope, and the epithelium could not be seen at all. The commencements of the lymphatics were filled with finely granular detritus; the vessels of the mucosa were much distended, and surrounded by extravasations of blood. In places the mucous membrane was detached from the muscular coat, which had a cloudy appearance.

A HISTORY OF CRIME.

A REMARKABLE trial has just been concluded in Paris, a trial which brought to light a long series of murders perpetrated in cold blood, and with no other apparent motive than the acquirement of a comparatively paltry number of francs. The convict Pel, aged thirty-six years, a watchmaker by trade, seems to have begun his nefarious practices as far back as 1872, at which date his mother died under circumstances which leave but little doubt that her decease was owing to other than natural causes. The next fatality that befell the unfortunate family was the death of Pel's wife, soon after her marriage. From the symptoms observed by the doctor consulted in the last hours of her life, there appears every reason to believe that she succumbed to the action of an irritant poison; moreover, the recent chemical analysis of the exhumed remains, conducted by MM. L'Hôte and Brouardel, supports the theory that the drug employed was some form of arsenic. These eminent chemists detected an appreciable quantity of the mineral—about one milligramme in 200 grammes of the liver and kidneys. The brother of Madame Pel suspected foul play at the time of his sister's death, but after consultation with some relatives the evidence of Pel's guilt was not deemed sufficiently conclusive; and from the natural desire to avoid a public scandal no further steps were taken to investigate the matter until just recently, when it transpired that Pel was charged with having poisoned his mistress, Elisa Böhmer, and disposed of her body by burning it in a stove. In the interval between these alleged crimes Pel had married again and had parted from his wife after the latter, together with his mother, had shown signs of severe gastric disturbance. Nor did his evil practices end with this record, for he is reputed to have attempted the lives of two servants, one of whom has been missing since she was last known to have been in Pel's company, the general belief being that she fell a victim to foul play. It was proved in every instance that he would have benefited by the death of the women with whom he was intimately connected, and that in more than one case he actually became possessed of a sum of money. He was charged only with the murder of his first wife and last paramour, and was found guilty, without extenuating circumstances, on the second count of the indictment. In his defence he urged that his mother died a natural death; that his wife succumbed to arsenical poisoning which she had administered to herself, as a remedy, in the form of Fowler's solution; and that his paramour, Elisa Böhmer, had left his domicile without telling him of her destination. The prosecution met these statements either with a direct denial or by showing that there was circumstantial evidence of their falsity. It was further proved by experiment at the Morgue, that a human body could be consumed by fire in a stove similar to the one found in the convict's room in the space of forty hours. In all probability the prisoner would have been acquitted had he been charged with only one offence, but the accumulated evidence proved too strong even for the proverbial sympathies of a French jury. The case confirms the belief—if confirmation be needed—that nothing is too horrible to deter a man imbued with the instinct of crime from carrying out his fell designs. Mother, wife, mistress, and servant were sacrificed by intent or act to the all-engrossing passion of a criminal nature. The foregoing history is replete with interest and information. It will serve to illustrate the pages of "legal medicine," but we doubt if it will act as a deterrent to others who possess the same promptings to murder which Pel inherited, developed, or acquired. Fortunately for society, such monsters are few in number, and yet the contemplation of their existence is enough to make the strongest shudder and grow pale.

THE CROONIAN TRUST.

THE decision of the College of Physicians, to dispose of the increased funds accruing from the Croonian Trust, by instituting lectureships on anatomy and physiology in relation to pathology and therapeutics, can hardly be regarded with unmingled satisfaction. Although in this way the difficulties of adhering to the original Trust may be surmounted, it is questionable whether the money could not have been utilised to greater advantage; for there is no disguising the fact, that the collegiate lectures are attended by comparatively few members of the profession at present, and if the number and extent of these lectures are to be greatly increased, the audiences will, we fear, diminish even more. We fully recognise the difficulties which the College had to overcome, especially as the sum in question would hardly suffice to endow a professoriate, the only reasonable alternative; but we could have wished that some other means of encouraging research and advancing medical knowledge had been conceived than the extension of the lectureship system, which seems to be amply enough provided for at present. Nevertheless, the adoption of this plan may lead to a more liberal remuneration of the Croonian lecturers, of whom two might be appointed annually to deliver a course of six lectures each - the one in pathology, and the other in therapeutics.

CHOLERA IN SPAIN.

CHOLERA is undoubtedly spreading in Spain. It is no longer limited to the province of Valencia and to Madrid, but is becoming diffused in adjoining districts. Castellon is now invaded, and twenty-seven persons have succumbed, while not only the villages on the border of the province of Murcia are suffering, but the city of Murcia is itself the seat of a serious outbreak of the disease, which threatens to equal in severity some of the more serious local disasters of last year. Altogether the last official bulletin announces the deaths of seven persons in the city of Valencia, forty-one deaths in the city of Murcia, and seventy-one deaths in the province. As yet we have no further confirmation of the report that cases have again occurred in Marseilles, but it cannot be anticipated that Southern France will much longer escape from a return of the epidemic. To prevent this invasion a decree has just been published, prohibiting the importation into France of bedding across the Spanish frontier. That the appearance of cholera in France has been already so long delayed is probably due to the cooler weather which has prevailed during the present season, but we may expect before many days have passed to hear of certain suspected cases, which will come to be acknowledged as soon as they are sufficiently multiplied to make concealment no longer a possibility.

TREATMENT OF ILEUS.

THE value and expediency of washing out the stomach in cases of intestinal obstruction, recently advocated by Kussmaul and Senator, have been discussed at the Berlin Medical Society (*Deutsche Med. Wochensch.*, Nos. 21, 22). Dr. Bardeleben had pursued the practice in cases of ileus, without in any instance obtaining a cure, and was impressed rather with the risk it gives of encouraging delay in resorting to laparotomy owing to the marked alleviation of symptoms which follows the measure. He also instanced the fact that symptoms of ileus frequently arise from conditions other than those of intestinal constriction, quoting a case of traumatic rupture of the bowel with peritonitis, and three cases of cancer, one of the pylorus associated with a large scrotal hernia, and two of the peritoneum, in which operations were undertaken for the relief of supposed strangulation. Such cases of course could not be benefited by washing out the stomach. Nor did he think it of much avail in true ileus. A man had a small inguinal hernia which he had reduced himself. Symptoms of internal strangulation arose, and in six days they became urgent. Treatment by opium, washing out the stomach, and enemata alleviated the symptoms for a few days; but on the sixth day laparotomy had to be resorted to. A constricting band was found and divided; but death ensued from peritonitis in five days. Bardeleben thought that a more favourable issue might have occurred if the operation had not been delayed owing to the amelioration produced by washing out the stomach. In another case, in which the symptoms were severe and the abdominal distension great, the constricted gut was found to be gangrenous. The necrosed part was excised, and the divided ends of the bowel sutured; but the patient died the next day. In a third case, marked by great distension, the seat of strangulation could not be detected on laparotomy. The bowel was opened at its lowest part, and much fæces escaped. This patient succumbed in *two days from peritonitis and collapse. Dr. Schmid showed* a specimen from a woman who had been ill for six weeks before admission into the Augusta Hospital. There had been complete obstruction for six days, and for two days fæcal vomiting. The stomach was washed out five or six times, with transitory relief; but death occurred in twenty-four hours. The cause of the obstruction was found to be the inclusion of a coil of ileum in a loop formed between the large intestine and the uterus, which were firmly adherent to each other. There was commencing gangrene, and, owing to the adhesions, it was clear that an operation could not have given relief. Dr. Kuester related three cases simulating ileus. A woman had suffered a long time from vomiting, which became fæcal. Washing out the stomach checked the vomiting, and nutriment could be taken; but the general condition not improving, laparotomy was performed, when the gall-bladder was found to have *been perforated by a gall-stone. This was extracted, the* rent in the viscus sutured, and the peritoneal cavity cleansed of extravasated bile; but peritonitis was already present, and the patient died next day. Another case of gall-stone leading to peritonitis was also submitted to laparotomy without avail. In a third case, where vomiting had lasted for six days, the obstructing cause was found on examination to be a massive parametric exudation. The stomach was repeatedly washed out, and the patient recovered. Whilst agreeing that the measure entailed delay in operating, Dr. Kuester thought it useful in doubtful cases as an adjuvant to expectant treatment. Further, the ill success of laparotomy is often due to the great distension of the bowel; and the general condition of the patient is an index to its performance. Dr. Hahn had performed laparotomy in twelve cases of ileus, and in no case could washing out the stomach have given permanent relief. Where the procedure was of use was in cases of fæcal accumulation, which could be just as well treated by ice-water enemata. Dr. Henoch, on the contrary, thought the palliative effect of the method a gain, and instanced a case where washing the stomach had succeeded when enemata had failed. He recommended its use in doubtful cases, and the resort to operation if the general condition was not thereby improved. Dr. Senator held that in cases where washing out the stomach palliated the symptoms, and in some of those in which a cure was obtained, there was not invariably obstruction from fæcal accumulation in the large bowel; and he confirmed the statement that this measure had succeeded when enemata had failed. He still adhered to the opinion that it was a procedure of great value. Dr. Wolff would employ it not only to possibly remove the obstructing cause, but because by relieving the stomach from its fæculent contents it places the patient in a more favourable condition for operation. Dr. v. Bergmann instanced the danger in fæcal vomiting of secondary gangrenous pneumonia from inhalation, which washing out the stomach would obviate. In reply, Dr. Bardeleben admitted the difficulties in laparotomy, but insisted upon its being done early. He was not opposed to washing out the stomach, for he had done it in many cases. The main difficulty in these cases lies in the arrival at a clear diagnosis and the impossibility of *formulating any general rule of treatment.*

SCARLET FEVER CONVALESCENTS.

THE problem of dealing most effectively and wisely with convalescents from scarlet fever cannot yet be said to be solved, though too much praise cannot be given to Miss Mary Wardell for her brave attempts to settle it. The magnitude of the question may be gathered from Sir Rutherford Alcock's statistics, showing that while in ten years, 1870 to 1879, 57,423 people died from small-pox in England and Wales, no less than 173,124 died from scarlet fever. Miss Wardell's Home at Brockley Hill, Stanmore, is still in need of funds to complete the arrangements and furnishing contemplated, and even to continue the present scale of work. In a well-ordered household it is easy to prevent the occurrence of a second case of scarlet fever. The problem which benevolence has to solve—whether personal or State benevolence is a grave question—is how to place the poor man in this respect at a similar advantage. Meantime those who are benevolently disposed will do well to assist Miss Wardell.

MONSTROUS SPERMATOZOA.

Gaillard's Medical Journal for May contains a short paper by Dr. Ephraim Cutter of New York, on "Variations in the Form of Human Spermatozoa." He figures some examples of two-headed and three-headed spermatic filaments which were observed by Dr. G. H. Salisbury in 1881, and gives a second figure containing examples of these deformities observed by himself in human semen, as well as two-tailed and three-tailed spermatozoa. Dr. Salisbury's specimens were obtained from pure semen; Dr. Cutter obtained his from semen mixed in the urine. The latter *writer suggests that certain* congenital deformities may depend upon monstrosities of the sperm, and *seems to hint* that a double-headed monster may be the *offspring of a* two-headed spermatozoon.

NEW TESTS FOR SUGAR IN URINE.

Some years ago Dr. George Hay pointed out, as others have done, the unreliability of Trommer's test for sugar in the urine. An article has recently appeared in the *Therapeutic Gazette* by Dr. Hay. It gives an account of an experimental investigation of the reactions of various cupric salts with grape sugar. Experiments have been made with cupric chloride, sulphate, nitrate, acetate, oxalate, citrate, tartrate, and acetate followed by tartrate, also with zinc sulphate followed by copper tartrate, zinc acetate followed by cupric tartrate, sulphate of aluminium followed by cupric tartrate, acetate of aluminium followed by cupric tartrate, protochloride of tin followed by cupric tartrate, acetic acid and acetate of lead followed by cupric tartrate. The tests are said to be much more reliable than any that have hitherto been proposed. Dr. Hay strongly recommends some of the tests for quantitative purposes. One general [illegible] pervades the whole of the tests, and this is the separation of substances which interfere with the reactions. We will describe two of the methods most strongly recommended. Thirty drops of a saturated solution of cupric acetate are added to two drachms of urine containing one-fifth of a grain of grape sugar. The mixture is heated in a bath of boiling water for ten minutes, and then cooled by immersion in cold water. A bulky precipitate results. The whole of the contents of the tube are turned on a filter; a few more drops of the acetate of copper are added to the filtrate, with a view to removing everything precipitable. If the fluid remain clear, a grain and a half of cupric tartrate is added, and then potash in excess so as to form an intensely blue solution. Heat is next applied, when the suboxide of copper is precipitated. Here is another method: Ten drops of a strong solution of chloride of tin are added to two drachms of urine containing one-fifth of a grain of grape sugar. An abundant pink precipitate results. The test tube and contents are heated and afterwards cooled by immersion and filtered. The filtrate must then be retested with a few drops of the solution of chloride of tin. If it remain clear, a solution of carbonate of soda is added till a faint alkaline reaction is obtained; heat is applied, and a yellowish-white precipitate of oxide of tin is thrown down; then filter whilst hot; the filtrate should contain no salt of tin. Tartaric acid is added to the filtrate until a faint acid reaction is present; then a grain and a half of cupric tartrate is added, and next potash in excess, with the production of a clear blue solution. Heat is applied. In five minutes the fluid becomes yellow; in ten minutes an orange-yellow precipitate forms of suboxide of copper. There can be no question of the neatness and cleanliness of these methods of testing for sugar, but they would involve too much labour and take too much time for ordinary clinical purposes.

THE CONTAMINATION OF CLOTHING.

Once more the dangers of home work in the tailoring trade have been brought before the public. At the Worship-street Police-court, a woman was convicted of having covered her child over with the military trousers she was making while the child was suffering from small-pox. In spite of the warning given, the trousers, eighteen pairs in all, were taken to her employers' shop without previous disinfection. The woman was fined £1. But for one case thus discovered scores remain concealed. The difficulty of earning even the most meagre subsistence in the tailoring trade is so great that we can well understand the temptation to deny the existence of such infectious disease as may stop the supply of work. It is not fair or reasonable to expect persons on the verge of starvation to risk the little they earn for the sake of preserving the health of others. Either home work must be entirely abolished, or else all who work at home must be certain of receiving ample compensation when such work is stopped by the outbreak of fever. Otherwise the great majority of workers will never consent to voluntarily reveal what may incapacitate them from earning their living. At a recent meeting of working tailors, convoked for the purpose of founding a co-operative clothiers' manufactory, one of the speakers frankly confessed that he had used the clothes he was making as bedding for his children when they were down with scarlet fever. In the street of Spitalfields, where he lived, small-pox had visited a number of houses inhabited almost exclusively by tailors who worked at home. No precaution had or would be taken while the dread of starvation was the uppermost thought in the mind of the unfortunate East-end tailors. In such quarters public workshops under official supervision, where neither Factory nor Sanitary Acts could be defied, would render a great service. The public would also do well to inquire before purchasing whether the clothes came from a workshop under the Factory Act, and thus bring some pressure to bear upon the master tailors.

NEPHRECTOMY IN LEYDEN.

Prof. van Iterson of Leyden reports a case of nephrectomy in a female patient aged twenty-six. For many years she had suffered more or less from renal colic; a tumour then appeared in the left lumbar region, which after a time was opened by free incision, a considerable quantity of pus being discharged. The urine, which had previously contained pus, now became free from it, and, though strongly acid, it at no time contained calculi. When she was admitted, two years later, under the Professor's care, the fistulous opening was still discharging pus; there was a certain amount of infiltration of the skin in the neighbourhood; the urine contained a few pus-corpuscles, vaginal epithelium, and mucus, but no albumen, the solids being 3·1. About 800 cubic centim. were passed per diem. On consideration of the history of the case, it was thought probable that the cause of the suppuration of the kidney was a calculus, but that, after free exit had been made for the pus, nothing had passed through the left ureter, the right kidney probably alone performing the secreting function. It was decided to operate, performing nephrotomy or nephrectomy, according to circumstances. An incision was made from the eleventh rib to the crest of the ilium. On examining with the hand, an opening was found leading to a cavity in the kidney, which was much enlarged and freely movable. An aseptic ligature having been firmly fastened round the pedicle two fingers' breadth from the organ, this was severed and removed. The wound was dressed with iodoform and iodoform gauze. The patient rapidly recovered. The kidney, which was examined by Herr Siegenbeck van Heukelom, demonstrator of pathological anatomy, was bean-shaped, elastic to the touch, rather less hard than fibrous tissue, and measured in length 150 millimetres, and in breadth 45 millimetres below and 60 millimetres above the hilus, the upper part being lobed. An irregular aperture admitting two fingers existed above. On section the substance of the kidney was found to be riddled with cavities, the walls of which varied in thickness from 4 to 12 millimetres; their structure was seen under the microscope to consist of highly degenerated renal tissue. No calculi were found. The cause of the renal suppuration could not with any certainty be determined, but Professor van Iterson thinks it probable that the origin was due to lithiasis, the attacks of colic being perhaps caused by the passage through the ureter of small calculi, which escaped observation when voided. Ulceration and sloughing may also have been induced. He considers that in cases of pyonephrosis and paranephritis operative measures should usually precede the external bursting of the abscess, as the results of subsequent nephrectomy are not favourable; still where, as in this case, the adhesions are easily broken through and the kidney can be readily removed, this operation may fairly be undertaken in preference to that of nephrotomy, which, though it may result in a cure, requires a long time to effect it, and is besides very uncertain, its risks, too, being scarcely counterbalanced by the chances of a few of the glomeruli and pyramids being rendered capable of resuming their functions.

THE ST. ANDREWS GRADUATES' CONVERSAZIONE.

THE conversazione of the St. Andrews Graduates Association, held on Wednesday evening in Chandos-street, was largely attended, and was in every way a marked success. The guests—who were received by Dr. Richardson, F.R.S. (President), Dr. Paul (Treasurer), Mr. Menzies (Honorary Secretary), and Dr. Christie—included Mr. J. T. Wood, the explorer of the Temple of Diana at Ephesus, Dr. John Lowe, Mr. Hyde Clarke, Sir James Cockle, Dr. Ord, President of the Medical Society of London, Major Childs, Dr. Crichton Browne, F.R.S., Serjeant Robinson, Sir Patrick Colquhoun, Dr. Hack Tuke, Col. Brabazon, Mr. A. Wynter Blyth, Dr. Spencer Cobbold, F.R.S., and a very large number of graduates and their ladies and friends, who filled the rooms and took part in the enjoyments of the evening until a rather late hour. The chief feature of the evening, and a novel one, was an address by the Rev. Dr. Lansdell, D.D., the well-known Siberian traveller, on Bokhara and Khiva. The lecturer, who put on the grand Oriental dress which had been presented to him by the Ameer, gave some extremely curious and interesting facts about the nomadic tribes whom he had visited, and about some of the diseases to which they are subjected; and after speaking for nearly half an hour and answering many questions, received a most hearty vote of thanks on the motion of the president, who added a message from Dr. Schliemann, regretting that absence from England prevented him from being present.

A CASE OF TRAUMATIC ANEURYSM.

IN the *New York Medical Journal* for May 23rd Dr. Theodore McGraw of Detroit relates an interesting case of traumatic aneurysm of the subscapular artery. The patient was a Pole twenty-seven years of age, who received three stabs about the shoulder in December, 1881, one of which was followed by an enormous extravasation of blood that was in due course absorbed. Three years later he came under Dr. McGraw's care with a rapidly growing pulsating swelling in the axilla, which had all the usual characters of an aneurysm. There was no alteration of the radial pulse. Its increase in size was so rapid that treatment had to be resorted to at once. The first step of the operation was to make an incision above the clavicle, through which the subclavian artery could be compressed. A free incision was then made over the tumour, and carried through the pectoralis major muscle, and attempts were made to detach the thick sac of the aneurysm from the surrounding structures. When this step of the operation was about half completed, the sac ruptured, and thinking that the attempt to isolate it must be abandoned, the sac was freely laid open, and the mouth of the artery controlled by the finger; but after many efforts it was found quite impracticable to free the mouth of the artery and to throw a ligature around it, for the sac was formed of very dense tissue, and was firmly adherent around the wounded artery. Dr. McGraw thereupon returned to his original plan, and with ease separated the fundus of the sac from the ribs and the anterior and posterior walls of the axilla, and then ligatured its neck. After this the axillary artery was with comparative ease freed and tied above and below the origin of the subscapular branch, which was found to open into the aneurysm within half an inch from the parent trunk. Arguing from this case, Dr. McGraw advises that while Syme's operation is suitable for cases of ruptured artery, it should not be adopted for traumatic aneurysm where there is a well-formed sac. It is pointed out that it may be impossible from the interior of an aneurysm to free the artery sufficiently to ligature it without imperilling contiguous arteries, veins, or nerves, while the detachment of the sac may be a comparatively easy and rapid procedure if done systematically. A ligature can then be tied round the neck of the tumour, and all danger of hæmorrhage avoided, and if the fundus of the sac be cut away the field is comparatively clear for the final steps of the operation. It is undoubtedly a dangerous and difficult matter to clear an artery from the inside of the sac of an aneurysm, and where the sac is sufficiently dense to permit of it, the plan of operating prepared by Dr. McGraw offers decided advantages.

STATISTICAL SOCIETY.

THE Statistical Society intends to hold its Jubilee Festival on Monday next and the two following days. The meetings will be held in the theatre of the London University in Burlington-street, and, it is expected, will be attended by a considerable number of the most distinguished statisticians of Europe and America. The first meeting will take place on Monday at 3 P.M., when the president's address will be delivered, and papers read by Dr. Mouat, Mr. Giffen, and M. de Foville. On Tuesday the subjects of the papers will be "Uniformity of Statistics, and the Numerical and Graphic Methods," and on Wednesday Professor De Neumann Spallart will give a *résumé* of the results of the International Statistical Congresses, and sketch of a proposed form of International Statistical Association. From the names of the distinguished members and visitors by whom the papers are to be read we are justified in anticipating that they will be of high quality and likely to give rise to interesting discussions. The annual anniversary meeting of the Society and the jubilee dinner take place on Tuesday, and the Society gives a *jubilee conversazione* at the South Kensington Museum on Wednesday evening. The Lord Mayor has invited the council of the Society and the foreign visitors to luncheon at the Mansion House on Monday previous to the meeting at Burlington House.

STRAPPING THE TESTICLE.

AT a recent meeting of the New York Surgical Society Dr. Post mentioned a case of gonorrhœal epididymitis, in which he had employed strapping the testicle in the subacute stage. The President of the Society, Dr. Weir, opened the discussion on the case, and expressed an opinion adverse to the value of this means of treating swelled testicle, and in this opinion he was supported by several subsequent speakers. Dr. Post, however, strongly contended for the value of this old-established treatment. We believe that, were the subject raised at any of our British Medical Societies, a similar difference of opinion would be found to exist. There is no doubt that it is not an easy matter to strap the testicle well; even the preliminary process of shaving the scrotum is not a simple matter, as anyone who for the first time attempts to do it thoroughly quickly learns. The circular turn of strapping round the spermatic cord is liable to cut into the thin skin, and eczema of the scrotum is not an infrequent result when strapping is placed next the skin. When lint is placed between the skin and scrotum, it is apt to be thrown into folds by the firmer strapping and to lessen the equable pressure of the latter. However, by care and the skill obtained by practice, it is quite possible to get over all these difficulties, and, either by the use of a thin elastic bandage or of a linen bandage beneath the strapping, to apply firm and equable pressure to an enlarged testicle. The advocates of this plan of treatment may fairly attribute much of the opposition to it to the difficulties met with in carrying it out and to the failure to overcome them. But we must not imagine that this explains it all. There is no doubt that in the great majority of cases of epididymitis strapping the testicle is neither required nor advantageous. As soon as the acute inflammation subsides, the inflammatory products are for the most part rapidly absorbed and leave but a trifling induration behind. It is only in cases where this does not occur, and where the epididymis continues considerably swollen, that circular compression is of real value, and in these cases it is very valuable. But it is particularly indicated in subacute inflammation of the body of the testicle itself. The treatment is most easily carried out when the organ is considerably enlarged, and it is in these cases that it is most useful. It cannot, of course, be attempted in acute inflammation; and in other cases we should say that the greater the swelling of the organ—the larger the amount of inflammatory exudation to be absorbed—the greater is the value of strapping the testicle. In other words, the easier to apply, the better the effect.

UNAPPRECIATED THRIFT.

At the recent annual meeting of the Medical Benevolent Society at Birmingham, the President made some remarks which deserve the attention of a wider circle than those who chanced to be present. After an existence of sixty-four years the Society has accumulated an invested capital which amounted to £10,705 on Dec. 31st last, and is steadily increasing. Registered medical practitioners within fifty miles of Birmingham are eligible as members of this Society, and within that radius upwards of 900 practitioners are included; yet at the close of last year only 264 members were on the books. Cases not unfrequently come to the knowledge of the Court of Directors urgently requiring assistance, when it cannot be rendered legally because membership had not been sought in due time; yet the subscription is at the [illegible] £2 1s.,—£1 1s. a year for twenty-one years, or £10 10s. if paid in one sum on admission. As, happily, only a small minority of members, or their families, come upon the funds, the Court is able to deal liberally with those who do; and the cases are not few in which sums varying from £20 to £40 a year are given for a great number of years. The excess of total income over total expenditure has for the last five years averaged £248 per annum; and the results prove that the widows of three members, whose entire payments were only £38 7s., received from the Society's funds no less an aggregate than £2927 10s. The radius of fifty miles from Birmingham, within which practitioners have a right to claim membership, includes nine county towns—viz., Derby, Hereford, Leicester, Lichfield, Northampton, Shrewsbury, Stafford, Warwick, and Worcester; also such industrial centres as Burton-on-Trent, Coventry, Dudley, Newcastle-under-Lyme, Walsall, and Wolverhampton. It is computed that over this wide area something like 700 additional practitioners might claim their admission to the Medical Benevolent Society, which is conducted on such principles as to allow of wide expansion in its operation, with the most perfect safety. The Society is registered under the Friendly Societies Act, and the secretary, Dr. Thomas Savage, of Newhall-street, Birmingham, will be happy to supply the fullest information to all eligible for membership. It being a point of honour with the directors and officers to observe the strictest confidence as to the name and position of the persons relieved, the Society cannot claim sympathy for special cases. Were it otherwise, the process of recruiting members might be easier. It is difficult to imagine in what apparently unlikely cases the funds of the Society become urgently needed for relief. When that becomes known, not an hour is lost in giving the necessary instruction to the treasurers, and they never lose a minute in giving it effect. These facts fairly entitle the thrifty Midland Medical Benevolent Society to a wider appreciation than it has yet enjoyed.

LYMPHO-SARCOMA OF TONGUE.

THE paper which Mr. Hutchinson contributed to the Royal Medical and Chirurgical Society on Tuesday last was one of much clinical and pathological interest. The case was that of a medical student who had had a morbid condition of the tongue, if not from birth, at all events from early life. The morbid condition would appear to have been one which, with Mr. Hutchinson, we may regard as a "congenital mole," having a tendency also to a nævoid condition. Such hypertrophies of lingual tissues are not in themselves of very rare occurrence, but they are nevertheless of much importance as clinical objects of study in addition to their pathological relations, and the remarks on their structure by Mr. Butlin and Mr. Barker were of much value. The chief point raised by the paper in question would appear to be the development of a sarcomatous tissue in the ordinary course of the life of this hypertrophic condition. To all appearances the case which formed the chief part of Mr. Hutchinson's paper was one in which, in the first period of its existence, the disease had no malignant characters. And even later on, when the patient was first seen in London, there was nothing except the size of the tumour to excite much alarm about it. There was no ulceration and no glandular affection. The removal of the very large if not the largest tumour of the tongue on record (weighing seven ounces), could only be effected by a division of the lower jaw and preliminary tracheotomy. The operation was successfully accomplished, and the patient enjoyed the next two years of his existence apparently in the best of health. The microscopical examination alone caused any ground for alarm, for such skilled microscopists as Dr. Klein, Mr. Butlin, Mr. Godlee, and Mr. Eve all testified to its sarcomatous nature. And they were right. At the end of two years the growth recurred at the cicatrix, and caused death by its rapid development. The case is one of much interest on account of the great size of the tumour, the great rarity of sarcoma of the tongue, and also as an illustration of the occurrence of malignant disease on the top of a congenital and apparently innocent hypertrophy of certain of the lingual tissues.

LUNACY CERTIFICATES FOR CLUB PATIENTS.

THE practice of club surgeons with regard to certificates required by members for purposes unconnected with the club or with their ordinary employment differs considerably, for while some surgeons are willing to give any number of certificates to enable a man to draw sick pay from other clubs with which the surgeon has no connexion, others make a practice of charging a small sum for such services. It would certainly be better if some common system were agreed upon regarding payment for club members' certificates, or if a definite agreement were made with clubs at the time of taking office. A case illustrating the importance of this has just come before Judge Pitt Taylor at the Woolwich County Court. A family had been entered many years ago as medical aid members, paying a penny a week each to one of the large industrial insurance companies. When the company gave up its medical aid branch, a private arrangement was made with the surgeon and the agent to continue it on the same terms as before; this was understood to entitle the members to attendance and medicines except during confinements. Recently one of the daughters became deranged, and it being necessary to send her to an asylum, the club surgeon filled up a form, another practitioner doing the same. The latter gentleman's fee of a guinea was paid without hesitation, but when the club surgeon sent in a claim for a similar amount, it was refused on the ground that the weekly payment covered it. As the surgeon took a different view, it was arranged in a friendly manner to test the case in the county court, with the result that the judge held that the medical officer of a club is bound to give *any* certificate required by a member, even a certificate in lunacy. He believed, however, that this was the first time the question has been raised. As this is not the view taken by medical men generally, it would be well to have the judgment of a superior court, but we understand the medical man concerned has no intention of appealing.

THE ÆSCULAPIAN SOCIETY.

ISLINGTON has long had a good Medical Society, founded by its best local practitioners, Cattlin, Clifton, Jackson, Kesteven, and others, and to which they and their younger neighbours brought the best of their experience; and this Society continues still to thrive. Perhaps not the least proof of its vitality is the appearance of a very vigorous offshoot of the old tree, yclept "The Æsculapian"—differing from the older Society in meeting in other than private houses, where the severities of the drawing-room need not hinder the odour of the morbid specimen or the more attractive odour of the "weed," whose devotees claim for it that it loosens the tongue, sharpens the brain, and makes a society ever so much more social. The Æsculapian has justified its existence in more ways than by the innovation of smoking, notably by a volume of Transactions containing some very excellent contributions on subjects in every department of medical practice. The annual dinner of the Society was held on the 5th inst., in the Holborn Restaurant, under the most genial presidency of Dr. Lough, when the Society showed a wonderful richness in musical and social qualities, and gave to guests the impression that it was a very creditable representation of the body of general practitioners, of which it boasts to consist almost exclusively.

INFECTIOUS DISEASE AND SCHOOL ATTENDANCE.

ONE of the chief considerations in the working of a general and compulsory system of education is its adaptation to the case and circumstances of particular scholars. Proof that some degree of pliancy is necessary is furnished by the evidence brought forward some time ago of the unequal pressure of a common method in teaching, and this has paved the way for certain measures of reform. Another difficulty which has to be allowed for, but might be thought too obvious for regulation, presents itself in the very frequent prevalence in childhood of infectious fevers. It would seem, however, that some recognised rule for such cases is still wanting. Thus, in an instance lately reported the mother of a family, several of whom had measles, felt herself obliged to send one of her children to school out of the infected house in consequence of repeated notices from the School Board officers. The latter, we presume, were imperfectly informed as to the facts. Let us now recall the usual surroundings of such a child. His home very frequently consists of one room, the hospital for the time being of sick brothers and sisters. If the family be large, it may occupy a flat. The rest of the house is probably tenanted by another family or more than one, healthy or not. In any case, the amount of house-room will vary with that somewhat uncertain quantity, the father's work. Disinfection, fortunately far more common and more easy than formerly, gives no absolute immunity, nor, indeed, is it always resorted to. Then we have to remark the danger to others implied in the vagueness of the symptoms of invasion. During this period infection is mustering its forces almost unobserved; and it is then that measles in particular is most infectious, though still obscure. The mere statement of these facts should convince one that the apparently sound member of an infected family cannot safely mix with other children unless he live separately while at home. We have shown how difficult it is to obtain this separation. It has accordingly been long recognised by other than Board schools, that where isolation of the sick is impossible the healthy children cannot attend school. Without a provision of this kind, schools in general, and especially the National and Board schools, must become in a greater degree than they now inevitably are starting-points for many cases of contagious and infectious disease.

TAXATION OF BEER OR TEA.

MR. JOSHUA FIELDEN is at serious variance with Mr Gladstone and Sir Charles Dilke in reference to the amount of the existing taxes on beer and tea respectively. W cannot pretend to decide when such doctors disagree; bu we must express our decided preference for increasing th taxation on beer and spirits as compared with that on tea The plain facts on this subject are the best for purposes o guidance. The present taxation of beer is not enough t hinder the consumption of an amount of it altogether i excess of the physiological or dietetic requirements of th body. It stiffens the joints and besots the intellect of th labouring classes, who are now to acquire such momentou functions in the State. To talk of taxing the poor and no the rich with an income tax of eightpence in the pound i slightly suggestive of uncandour; but in the interest of th working classes and of the State alike, let us tax articl that can well be spared, and not articles of refreshing die

SUCCESSFUL PORRO'S OPERATION.

La Gazzetta degli Ospitali of the 7th inst. reports th Professor G. Calderini performed Porro's operation on th 10th ult., in the Gynæcological Institute of the Universit of Parma, on a woman greatly deformed by rickets. Th operation was performed several days before the labou period, and Porro's method was slightly modified. On ex posing the uterus, a small transverse *incision* was made int it, and the uterine tissue torn in the same direction wit the fingers. The pedicle was constricted with an elasti ligature, and fixed to the abdominal wound by long inter secting needles. The superficial sutures were removed o the fifth day, and the deep ones on the eleventh, union by first intention having resulted. The third dressing wa renewed on the eighteenth day, and the fourth on th twenty-first; the pedicle, not having then become completely detached, was divided. The patient's highest temperature was 37·5° C. The child is alive and well.

TAPEWORMS AND HYDATIDS.

AT the soirée of the Royal Society held last week thi subject was pretty fully illustrated by a series of pre parations exhibited by Dr. Cobbold. Amongst the mor interesting specimens were a set of slides of Tænia echino coccus, kindly lent for the occasion by Dr. J. Davie Thomas, in illustration of his paper "On the Rearing o this Tapeworm by feeding Dogs with Human Hydatids. Specimens were shown of thirty-two and forty-two day old respectively. To compare with these, Mr. Edwar Nettleship's Tæniæ, forty-seven days old, reared by feedin [illegible] hydatids from a sheep, were also shown. Dr. Cobbold supplemented these by exhibiting three other kinds of canine [illegible], which he reared by experiment from their appropriate scolex forms. Several varieties of hydatids, such as Echinococcus hominis, E. veterinorum, and the rare E. multilocularis were included. The completeness of the series will be better understood by the enumeration of the canine and feline tapeworms shown—Tænia marginata, T. serrata, T. litterata (often called T. canis lagopodis), T. cucumerina, and also the variety known as T. elliptica, T. cœnurus, T. crassicollis, Bothriocephalus latus, B. cordatus, B. dubius, and B. felis. Several of the slides were originally contributed by Professor Leuckart of Leipzig and Dr. Krabbe of Copenhagen. The last parasite on this list was only recently identified from amongst a set of entozoa contributed by Dr. Bancroft of Brisbane.

LEUCOMAINES.

In the *Bull. Soc. Chim.*, A. Gautier, writing on the action of bacterial ferments on albuminoids, by which certain poisonous alkaloids are produced, says that these seem to be identical with those commonly known as ptomaines; and proposes that, as they are constant and necessary principles in the normal excretions of living organisms, and have been detected in the saliva, urine, muscular juices, sweat, and also in numerous glands, they should be called "leucomaines" ([illegible], the white of egg). They are mostly poisonous, crystalline, and give crystalline platino-chlorides.

EMETICS IN CASES OF FOREIGN BODIES IN THE AIR-PASSAGES.

A. Häcker mentions in the *Vrach* some cases of foreign bodies in the air-passages. In one of them the patient, a child of five years of age, had been given a powerful emetic by a "feldsher" (a hospital sergeant), and when Dr. Häcker arrived the child was almost moribund. He thinks that, as a rule, emetics do no good in these cases, and may produce serious mischief.

SOME OF THE CHEMISTRY OF CHOLERA.

An investigation of the changes which epidemic cholera produces in the bile and alvine dejecta has been conducted by M. Gabriel Pouchet. The author has made six analyses of bile collected from the gall-bladder very soon after death from cholera. A large proportion of albumen was found in the glutinous fluid. The albumen forms, with the mucin, the greater part of the residue resulting from evaporation. The bile was very watery. In every case the presence of leucin, tyrosin, glucose, and fatty globules mixed with fatty acids and cholesterine was detected. After separation of the albuminoid matter by strong alcohol, the colourless liquid precipitated by acetic acid become slowly coloured of a brownish-green. The precipitate produced by acetic acid is formed of cholic and choloidic acids and dyslysin, which shows that a decomposition of biliary salts may take place in the gall-bladder. The alvine excreta were almost [illegible], very watery, and contained a considerable proportion of [illegible] and chloride of sodium. The vomit frequently contained the elements of bile. Ptomaine extracted by [illegible] with chloroform presented itself as a colourless liquid, having the characteristic odour of pyridic bases, changing in air and light with great rapidity, and acquiring a [illegible] colour, and afterwards a brown. A marked [illegible] reaction is given, it forms a chlor-hydrate which [illegible] by elevation of temperature or in a vacuum. Attempts to purify the alkaloid were made, but the purified product had but little toxic effect when injected under the skin of guinea-pigs, though the original [illegible] killed a frog in less than two hours.

It is stated that Lord Shaftesbury, in view of the extreme improbability of the Lunacy Acts Amendment Bill (to certain clauses of which it will be remembered he strongly objected) becoming law during this session, has consented to resume his position as chairman of the Lunacy Commission. As regards any future proposed legislation on the subject, his lordship is understood to have reserved to himself complete liberty of action.

The outbreak of small-pox which has taken place at Burslem has spread to other districts, and serious alarm is experienced in the other towns of the Potteries, which are all grouped together. The Sanitary Committee of the Burslem Town Council, recognising the special importance of isolation, have ordered two more hospital tents, to contain twelve beds.

We learn that, a memorial having been recently forwarded to the Home Office from medical practitioners of Derby praying for the release of Dr. Bradley, Sir Wm. Harcourt has replied to the effect that, having considered all the circumstances, and consulted with the judge who tried the case, he does not see ground for interfering on the prisoner's behalf.

The members of the United Faculties' Club of the University of London dined together on the 17th inst. at the Star and Garter Hotel, Richmond. Dr. Langdon Down occupied the chair, and was supported by Sir John Lubbock, Dr. Storrar, Mr. Cooper Forster, Dr. Bristowe, Mr. J. G. Fitch, Mr. Magnus, and others.

The patient from whom Sir Henry Thompson recently removed by the supra-pubic method a calculus composed of pure uric acid weighing 14 oz. avoirdupois, as recorded in our issue of May 2nd, has made, we learn, an excellent recovery. Full details of the case will be published in our columns in due course.

The *Revista de Pharmacia e Drogaria* of Rio de Janeiro states that a free school of pharmacy has been founded by the Pharmaceutical Institute of that city, and is to be maintained at its expense.

Dr. Monochovez, prosector in the University of Moscow, has been appointed Lecturer in Physiology in the Forest Academy of Petrovski.

THE HOSPITAL SUNDAY FUND.

The total amount received on behalf of the Metropolitan Hospital Sunday Fund up to the time of our going to press is £13,450 13*s.* 5*d.* Many amounts are less than those paid from the same places last year, but there are on this occasion several new contributors.

The following are the principal contributions which have so far been received on behalf of the Fund:—St. Michael, Chester-square (Canon Fleming), £251 4*s.* 6*d.*; St. Jude's, £702 4*s.*; Westminster Abbey, £195 7*s.* 8*d.*; St. Paul's Cathedral, £161 6*s.*; Union Chapel, Islington, £100 17*s.* 8*d.*; Metropolitan Tabernacle, £[illegible]; Great Synagogue, £240; St. Mark's, North Audley-street, £218 5*s.* 2*d.*; St. Margaret's, Westminster, £172 19*s.* 6*d.*; The Temple Church, £172 14*s.* 5*d.*; St. Barnabas, Kensington, £[illegible] 7*s.* 2*d.*; Quebec Chapel, £256 7*s.* 3*d.*; Messrs. Reid and Co. (a further donation), £200; St. Andrew's, Wells-street, £110 12*s.* 2*d.*; St. Mary's, Bryanston-square, £108 10*s.*; St. James's, Piccadilly, £120 10*s.* 3*d.*

A correspondent calls our attention to the case of St. Peter's Church, Vere-street, where the annual collection now averages more than £200, whereas when the present incumbent (the Rev. W. Page Roberts) took office the sum contributed by the congregation was only about £[illegible].

REPORT
OF
The Lancet Special Sanitary Commission
ON
MARSEILLES AND TOULON.

No. I.

From Toulon and Marseilles the cholera has menaced all Europe. The public opinion of England, as well as of France, has therefore some right to urge the duty of adopting measures likely to prevent these towns becoming once more a source of special danger to the entire European community. While the epidemic lasted it could not be expected that the authorities would undertake any important public works. To nurse the sick, to observe, as far as possible, the cause and history of each case, and to disinfect in a wholesale manner, sufficed for the moment. Now, however, a year has elapsed since the first outbreak of cholera at Toulon. A long winter afforded the necessary time to select and enforce the sanitary improvements most suited to meet the risks of the present summer. Already two cases of cholera are reported from Marseilles. This would be a matter of little importance if, in the interim, energetic precautions had been adopted. The lesson to be derived from last year's epidemic was sufficiently severe to justify the hope that it would not remain unheeded. Unfortunately at Marseilles, internal strife and factious divisions within the ranks of the municipality seem to have paralysed the authorities. They display more eagerness in denying the evil than in seeking its remedy. Nor is local public opinion sufficiently enlightened on sanitary matters to bring a wholesome pressure to bear upon the administration. The town still remains in a deplorable condition. Little or nothing has been done. Faith in the efficacy of quarantine regulations survives the late deplorable experiences, and yet the means taken to purify infected ships are altogether untrustworthy.

We carefully inquired from the port sanitary authorities what system of disinfection was enforced, and ascertained that the purification of ships was left very much to the discretion of the captain. In many cases it simply meant a good wash down, with the use of a little disinfectant solution. Thus there is no security whatever that the disinfection is absolute and capable of killing every known living organism. When fumigation is practised on board ship it seems to be the custom to wash first and fumigate afterwards, thus exposing the operators to considerable risk of contagion. On the other hand, the quarantine station formed by the union of the Pomègue and Ratoneau islands is better organised than was reported at the time. Contrary to what was then said, the new arrivals did not have any intercourse with those who were about to leave; while the general installation of the quarantine station, which the courtesy of Dr. Marrion enabled us to visit carefully, offers many and great sanitary advantages. The site is most healthy and beautiful, and the accommodation ample and economical.

With regard to the town of Marseilles itself, it should first be noted that the water-supply is exceptionally abundant. Strange as it may seem, however, this very abundance has given rise to a danger on which we cannot insist too strongly. The amount of water distributed being more than sufficient to fill the cisterns, these latter were supplied with overflow pipes that communicate with the drains. In many cases the cistern is placed uncovered in the closet, and such connexion with the drains offers more than usual risk. It is needless to say that traps are utterly unknown. At the bottom of the soil-pipe there should be a *tinette* to retain the solid material, but as a rule this is not used. The pipe continues under the house till it reaches a sort of catchpit placed under the causeway of the street; here the water deposits more than a cubic metre of solid matter, while the liquid from the surface of this little cesspool overflows into the sewer. There is no dip-stone in this catchpit, so that it does not act as a syphon, but the emanations from the sewer, from the catchpit, and the huge insufficiently flushed drain-pipes travel back unhindered into the apartments and into the cistern that holds the drinking water. Thus is the excellence of the Marseilles water-supply compromised. Surely the overflow pipes from the cisterns could be trapped with but little difficulty or expense. The catchpits might also be abolished, and as a temporary measure *tinettes* or movable pails employed in their stead. The fear of solids reaching the sewer is sufficiently obviated by the wire filter of the *tinette*.

These remarks, however, only apply to the more modern and wealthier parts of Marseilles. In the old town and poorer districts there are no such innovations as closets, catchpits, *tinettes*, or soil-pipes. It is doubtful whether there existed a single closet in Marseilles before the Revolution of 1848. It was and still remains the custom for the inhabitants to empty their vases into the gutter, though some throw everything from the window into a back yard, where it forms a foul manure heap till such time as it attracts the attention of a particularly bold and conscientious scavenger. Altogether Marseilles possessed at the time of the epidemic 48,000 metres of sewers, but the streets of Marseilles reached the total length of 225,000 metres. M. Guérard, the port engineer, has carefully dotted on a large map of the town every known case of cholera. The sewers are also drawn on this map, and we are thus able to realise at a glance that all the roads where sewers existed were remarkably exempt from cholera. This rule does not only apply to the large and well-ventilated streets, but also to narrow, poverty-stricken thoroughfares such as the Rue de la Guirlande, which runs through the old town from the Hospital to the Mairie, and is the only street in this part of Marseilles that possesses a sewer.

From these striking facts we cannot, however, conclude that sewers suffice to prevent cholera. The absence of sewers did not alone contribute to facilitate the outbreak of cholera. It was also noted that the disease prevailed with greater intensity in the streets paved with round knobbly little stones that readily allowed the moisture to sink into the earth. As the soil is either thrown directly into the streets or finds its way to the gutter after filtering through a *tinette*, which only retains a portion of the solids, it will be readily understood that the more porous the road the more thorough the infection of the ground. Also all private wells are not yet abolished, and, being dug in ground which has received the filth of ages, their water is highly contaminated. The marked decrease in the death-rate of Marseilles when the purer water of the Durance was first introduced is a clear proof of the dangerous nature of private supplies, and the abolition of wells should not be allowed to remain an optional matter. Not only in the town, but also in the suburbs, it will be found that most cases of cholera come from streets or districts that presented special sanitary defects. Thus, at the lunatic asylum Dr. Pons, who was in charge of the male wards, failed to trace any case of direct transmission. Every suspicious case of diarrhœa, &c., was transmitted to a ward of observation. Nearly all whose symptoms developed into true cholera came from the epileptic wards, where, apart from the naturally uncleanly habits of the patients, the drainage and ventilation are exceptionally bad. Others coming from more wholesome parts of the building, which contains altogether 1100 patients, soon recovered, and did not contract the cholera from the true cases with which they had mingled.

A little further on, in the suburb of the Capelette, nearly all the cases seemed connected with a little stream that winds in and out of the village. This stream, about a yard wide, is quite clean on entering the village, but on leaving the village we measured more than a yard deep of greasy, black, foul mud at the bottom of its bed, and the water was of an inky colour. The habits of the inhabitants of the village are filthy in the extreme. In some houses, where the brook passed under the kitchen or basement, a little hole was made in the floor. This served as the family closet, and was proclaimed a convenient and cheap way of getting rid of all soil, slop-water, and other refuse. In a rambling building, subdivided into sixteen tenements, where twenty cases and fifteen deaths occurred, we observed that the only accommodation consisted of a large masonry box or tank capable of holding four cubic metres of soil. This receptacle was wholely uncovered, was infested with thousands of flies, stank abominably, and its fæcal contents were constantly stirred up as each tenant came to empty his vase into this substitute for a watercloset. Crossing the main street, we visited a house where the brook ran down the side of the back garden. Here there were two wells; one within a yard and a half of the brook supplied the drinking-water, though it sometimes "smelt nasty"; the other well, a little farther off, and perhaps less contaminated, was not used because a dead baby had been found in the water. Two deaths from cholera were noted in this house. In the middle of the garden, and touching the brook, was a wooden donkey-shed and what was called the closet. It simply consisted of a hole about a foot deep dug in the earth, where the soil remained exposed to the sun, the liquid portion filtering through the earth into the brook. At the farther end of this back yard or garden we entered a sort of barn, where eighteen Italian labourers were allowed to sleep on straw. Among these latter there were two more deaths from cholera. Another house, which had been specially visited by M. Clemenceau, and in which nine cases and seven deaths are stated to have occurred, disposed of its sewage in a sort of well dug in the middle of the first out of two back yards. The soil being porous absorbed whatever was thrown down. In the second back yard two little wooden huts were built, measuring each two metres. They were just big enough to hold a bed, and were separated from each other by a foul midden. Here, exposed to the rain, the foul stenches, the damp from the saturated and poisoned soil, protected only by a few slender boards, wretched people slept, sometimes three in one bed. This abominable state of affairs is all the more reprehensible, as it is due solely to the supineness of the authorities. Without any extra expenditure of money or the enactment of any new law, it could at once be abolished. A regulation already exists to the effect that every house that is not provided with a cemented and ventilated cesspool shall employ a *tinette* or movable pail. To carry out this regulation, a contractor is ready to supply a clean, empty *tinette* every week, removing the pail that is full, for the very moderate charge of sixteen shillings per annum. Yet, in spite of this facility, the proportion of houses at the Capelette provided with *tinettes* amounts to only 44 per cent. of the total number.

During the epidemic the greatest courage and devotion were displayed. A help committee was constituted that penetrated every centre of infection and rendered practical assistance to those who were suffering. The members of this help committee were modest, simple, brave men, unknown to fame, and who have had little or no share in the decorations and honours showered upon the town by the Government. At the Capelette, M. Vaud, a working builder, was foremost in doing whatever was most unpleasant yet most necessary. But now that the epidemic is over these men have retired from the scene, and matters have relapsed into the same abominable condition which so favoured the outbreak of cholera. A huge sewer, projected five years ago, is now being constructed at the Capelette; and in the town, at the cost of £12,000, three thousand metres of sewers are being added to those that already exist, yet this is all done without any general scheme of drainage. Pending the adoption of some definite system, and the gathering together of the enormous sum necessary for its realisation, it would be more practicable to enforce the due observance of such regulations as do exist. What we term the pail system is actually applied to a large number of houses in and about Marseilles. It is a method that affords many advantages; some hygienists even go so far as to consider it the safest of all systems, and its application is susceptible of rapid extension. By closing the overflow allowed in some of the *tinettes* we have perfect pails, and their removal every two or three days will secure the town against a continuation of the present wholesale contamination.

One sewer at the Joillette, another at the Prado, have their outfalls into the sea; all the rest flow into the old port, and bring so much refuse down that the harbour has to be dredged every year, and something like 70,000 cubic metres of solid deposit taken out. The water is foul in the extreme, and both typhoid and cholera among the sailors sleeping on board in this old port was the natural result. The gutters, which contain the greater part of the house drainage of Marseilles, likewise empty into this basin. M. Guérard, in his able report, proposes to construct a large main sewer round the port, but at a sufficient distance and elevation from the water to enable its contents to run eastward and empty by gravitation into the sea outside the town. On the port itself a much smaller sewer would receive what came from the lower portion of the town situated below the projected main sewer. At a given point the contents of the smaller sewer would have to be pumped up into the main sewer. These two sewers would cost about £48,000, and would, in any case, prevent the contamination of the port. Unfortunately, even this partial reform is not yet adopted.

THE TEACHING UNIVERSITY FOR LONDON: CONFERENCE OF MEDICAL DELEGATES.

THE third and concluding meeting of the Conference consisting of the Sub-committee for the Faculty of Medicine of the Association for promoting a Teaching University for London and the delegates of the various medical schools was held on Monday last, when the subjoined report was agreed to. After enumerating the members of the Conference the report runs thus:—

"The outline of the plan for a Teaching University was submitted to as follows: That it should be founded on (1) Faculties as constituent bodies; on (2) Boards of Studies representing the Faculties; and on (3) a single Governing Body.

"We approve of this plan, subject to the following observations:—

"1. The Faculty of Medicine should consist substantially of the teachers in the recognised schools of medicine, whether lecturers or clinical teachers, and whether in the strictly professional or scientific subjects. Some points of detail arising out of the special circumstances of schools may be left for settlement hereafter, it being understood that the intention is to put a liberal construction on the qualification for the Faculty in regard to those actually engaged in teaching. The examiners appointed by the University should also be members of the Faculty, whether actually engaged in teaching or not. The power to appoint additional or extraordinary members of the Faculty should be reserved to the Faculty. We consider that this power would be especially beneficial in the case of retiring members of the teaching staffs.

"2. The Board of Studies should be appointed by election, and not by nomination. There exists among us some difference of opinion on the question whether all elections to it should be by the whole Faculty collectively, or whether it is desirable to provide for some special representation on the board of the several recognised schools of medicine. We are agreed, however, to recommend that each school shall be entitled to return one member to the board, to be appointed by those members of the Faculty who belong to the school. Those of us who most strongly feel the need of keeping the elections as open as possible, consider that the existence of a desire for this amount, at least, of separate representation is a sufficient argument for conceding it; and, on the other hand, those who consider that under the existing conditions of the schools some separate representation is necessary, are content that the rest of the elections to the board should be open to the whole Faculty without restriction. The representation of particular classes of studies will, it is thought, be sufficiently cared for by the Faculty in electing. It is, however, very important to the successful working of the system that the board should have the power, and should use it freely, of formal consultation with other members of the Faculty in regard to special matters and particular studies. The benefit of the presence of examiners in consultation when the arrangements for examinations are under consideration is an instance of this; but provided they are regularly summoned to consultation on these occasions, we do not think it necessary in view of the difficulty of including them all, or of satisfactorily providing for a representation of them, that they should be *ex officio* members of the board, or be separately represented on it. The number of the board should be not less than twenty or more than thirty. Power should be reserved to boards of studies to consult, when necessary, with those of other Faculties.

"3. Of the governing body it is essential that at least one-third should be representatives of the Faculties, elected by their boards of studies, or, perhaps, in part by the Faculties direct. If any are elected by a Faculty direct, they should also be members of the board of studies of that Faculty.

Supposing the number of the governing body to be fixed at from twenty to thirty, not less than three elected members should be appointed from the Medical Faculty. It is very desirable, with a view to the union of the examinations of the University in one system with those of the Royal College of Physicians and Surgeons, that room should be found in the governing body for representatives of these Colleges; and that arrangements should be made by agreement between the University and the Royal Colleges for the joint conduct of examinations under a common administration, so far as they deal with the same subject matter and with students at the same stages of their career.

"All seats on the governing body and on the Board of Studies should be held for a term of years only.

"In reference to the functions and work of the proposed Teaching University, we desire to call attention to the following points:—

"1. We think it desirable, in regard especially to the scientific branches of medical education, that arrangements should be contemplated whereby, under the guidance of the Board of Studies of the Medical Faculty, without impairing the autonomy of the several schools, some concentration may be effected of the teaching in particular studies, but subject always to the provision of a sufficient number of centres to meet the circumstances of the case.

"2. It appears to be desirable to contemplate the foundation of chairs in this University (whether attached or not to any existing institution) with a view particularly to the prosecution of the higher and more specialised studies, adapted to those who have already taken their degree, and supplementary to the instruction provided by existing institutions."

Similar conferences are being held in connexion with the other proposed Faculties, and the result of their deliberations, with the action taken thereon by the executive committee, will probably be brought before a general meeting of the Association in the autumn, when doubtless a definite scheme of the University will be submitted.

THE SANITARY CONFERENCE AT ROME.

THE delegates to the Conference having returned from a visit to Naples and its neighbourhood, where they received an unbounded hospitality both from the Government and the local authorities, the sittings of the Plenary Conference were resumed on Friday, the 12th inst. Whether owing to the difficulty of securing sufficient unity of opinion amongst the different nations, or whether, as was alleged, with a view of enabling the several Governments to consider the conclusions of the Technical Commission, it was at once decided to ask the Italian Government to adjourn the sittings to a later date. Several important statements and documents were handed in to the President, and these will doubtless appear in the published Proceedings, but for the time being no opportunity has occurred for their discussion.

At a sitting on Saturday, the 13th, it was announced that the Government had assented to the proposed adjournment and had suggested that the sittings should be resumed on Nov. 16th. This was unanimously acceded to, and the Conference then came to an end.

So far the only proceedings registered are those of the Technical Commission, and they have certainly succeeded in eliciting the different opinions prevalent in Europe and other parts of the world as to the value of the several measures advocated for the prevention of cholera. Whether opinions so much at variance can ever be sufficiently reconciled to make it worth while to attempt the compilation of an International or even of a European code, remains to be seen. The British and Indian delegates left Rome during the course of the present week.

MARINE BIOLOGICAL ASSOCIATION.—A meeting in furtherance of the objects of this Association was held on the 13th inst., at Oxford. The aim of the Association is to establish one or more marine laboratories for naturalists on the coasts of the United Kingdom, such as exist at Naples and elsewhere. The fund already subscribed amounts to £8000, and £2000 more is needed. Cambridge University has subscribed £500, and Oxford is appealed to for a similar sum.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Builth Rural District.—Dr. Herring gives a satisfactory account of the progress made in improving the sanitary condition of this district. During 1884 the death-rate was 12·28 per 1000, only three deaths being attributed to zymotic diseases. Of three cases from typhoid fever which occurred during the year, one was that of the sanitary inspector, who unfortunately lost his life. Water-supply has been provided to the village of Erwood, and steps are being taken with regard to other villages where the supply is deficient.

Middlesex and Hertford Combined Sanitary Districts.—An interesting chapter at the beginning of the annual report of these districts discusses conditions which are common to all. After referring to the manner in which cholera is known to spread in this country, Dr. Saunders points out the risks which are caused by the use of open privies and the ease with which a remedy can be found by the substitution of pails. A strong objection is taken to the exclusion of storm-water from sewers, this exclusion being done on the recommendation of engineers whose sole object is to bring schemes of sewerage within such limits as would be acceptable to sanitary authorities. On this point Dr. Saunders writes that "water-carriage sewage will soon be a misnomer, and already the effect of the removal of this natural cleanser and carrier is that sewers stink, and that open ventilators, which are the most rational and the best method of ventilating a clean sewer, are objected to." Attention is directed to the unsatisfactory closet accommodation in parochial schools, in several instances the health of the children having suffered in consequence. Of epidemic diseases, small-pox has been specially rife in Rickmansworth, where, during the epidemic, 1100 persons were vaccinated. Reference is also made to the increased prevalence of diphtheria in the kingdom; two severe epidemics of this disease occurred at Totteridge and South Mimms, and in both the disease first appeared in children attending schools where the closets were seriously at fault. In several districts enteric fever made its appearance, certain cases in the neighbourhood of Bernard Heath, near St. Albans, being due to a contaminated milk-supply from a farm which had given rise at the same time to an outbreak in the city of St. Albans, and in the previous year in the London parish of St. Pancras. The report contains evidence of careful inspection of all the districts and of steady progress in the improvement of their sanitary condition. The recommendations which are made for this purpose are well considered, and if adopted by the local authorities will do much to add to the healthiness of the various localities. The population of these combined districts is 91,051 persons, and the death-rate for 1884 was 15·7. The number of infants dying under one year of age was 25·5 per cent. of the total deaths, and the zymotic death-rate was 7·8 per cent.

Borough of Preston.—The report of the medical officer of health for this borough records the high death-rate of 25·53 per 1000, being slightly below the average of the previous ten years. The deaths from all causes under the age of one year form 34 per cent. of the mortality; as regards other large towns, the infantile death-rate of Preston is higher than that of all towns but one—viz., Leicester. Mr. Pilkington points out the effect which burial clubs have had upon infantile mortality in other towns; he does not, however, express any opinion as to whether Preston has been affected in a similar manner. The mortality from diarrhœa occurred mostly amongst the children of the operative and labouring classes, those of the Irish being comparatively exempt, a result which Mr. Pilkington believes to be due to the fact that the latter are almost always fed at the breast. Bronchitis added largely to the deaths of infants, and this he attributes to their removal in the cold of the early morning from warm and ill-ventilated rooms, where they had slept, to houses in which they are nursed while their mothers are at work. The zymotic rate of mortality was 5·15 per 1000 of the population; small-pox was almost absent, but measles was very prevalent in the latter part of the year, and the diarrhœal death-rate was as much as 2·91 per 1000. During the year a house-to-house inspection was made in a number of streets, and the necessary improvements of houses carried out. It has been decided to commence a destructor for the consumption of dry ashes and market garbage, and it is expected that it will overcome one of the difficulties with which the town has to contend. Special attention was given to the ventilation of the sewers, and the question of the erection of a public abattoir is receiving the attention of the sanitary committee.

Preston Port District.—Dr. Fisher reports that the attention of the authority was directed by the Local Government Board to the need for the inspection of shipping in view of the prevalence of cholera on the Continent, and Dr. Blaxall visited the Port for this purpose. There was, however, no importation of an epidemic or infectious disease during 1884.

Lytham Urban District.—This district has a population of 4373 constantly resident in the town, and during the year 1884 there were eighty-one deaths, giving a death-rate of 18·5 per 1000. The rate of mortality from zymotic diseases was only 1·1 per 1000, calculated upon five deaths from this class of disease. This is perhaps fortunate, for Dr. Fisher reports that the town is still without a disinfecting chamber for the purpose of disinfecting beds and bedding after infectious diseases. Only six cases of scarlet fever came under observation, and all occurred amongst visitors, and in all cases, as far as could be ascertained, the disease was imported. During the latter part of the year an epidemic of measles prevailed, but no deaths resulted. Houses and cottages, slaughter-houses and bakehouses, have been inspected, and an improvement effected in the drainage of one portion of the town where the sewer was specially defective.

Tendring Rural District.—It is estimated that the population of this district is 25,141, and during last year there were 411 deaths, giving a death-rate of 16·3 per 1000. The infant mortality is greater owing to an increased number of deaths from pulmonary affections and diarrhœa. This increase is attributed by Dr. Cook in part to improper feeding. A list of cases of zymotic diseases is given so far as they were known, but the zymotic death-rate is not calculated. Reference is made to five cases of typhus which occurred at Frating. These were, however, related to others which showed themselves in the previous December, and were fully commented on in the report for that year. The two diseases most prevalent in the district were measles and whooping-cough. The report points out the need for a system of sewers in several parts of the district, particularly at Bradfield and Parkeston; at Brightlingsea, where the sewers are also very defective, Dr. Cook recommends the tub system, so as to prevent injury to the oyster beds. At Clacton-on-Sea the new sewers are now completed, and satisfactory arrangements have been made for flushing them. Dr. Cook, however, does not regard their ventilation as perfect. The water supplied by the Clacton-on-Sea Water Company was found on analysis to be of very good quality.

Belper Rural Sanitary Authority.—In the Alfreton sanitary district there are 17,000 persons in thirteen different parishes, the death-rate in the total number is 12·96 per 1000, and varies in the different parishes from 4·17 to 18·91. In several villages efforts have been made to improve the water-supply by deepening the wells and protecting them from surface pollution. In one village typhoid fever occurred, and the locality of the disease is described as "a very unhealthy one by reason of the general filth and squalor of its surroundings." In this outbreak two persons died. There were but three other deaths from diseases of the zymotic class in the whole district. Mr. Gaylor reports that there is no hospital or means of isolating infectious diseases, and that a portable disinfector is much needed. Mr. Allen, medical officer of health to the Belper district, points out the need of a system of notification of infectious diseases, and for a central infectious hospital or cottage hospitals in different parts of his district. The water-supply to South Wingfield is described as scanty, and at the present time the inhabitants of the hamlet of Overthorpe are drinking water which is liable to contamination from the overflow of a brook which receives sewage from the town of Alfreton. The condition of the outfall at the sewage tank at Belper has caused much anxiety, attempts at purification having failed, and it is now proposed to change the position of the tank so that the effluent should be conducted over an open bed. The death-rate during the year is 13·7 per 1000, calculated upon a population of 17,626. The mortality of children under five years of age is considerably more than one-third of the total number of deaths. The zymotic disease during the year which has been most fatal was whooping-cough.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5563 births and 3168 deaths were registered during the week ending the 13th inst. The annual death-rate in these towns, which had been equal to 21·1, 21·0, and 20·5 in the preceding three weeks, further declined to 18·6 last week, a lower rate than has prevailed in any previous week of this year. During the first ten weeks of the current quarter the death-rate in these towns averaged 21·4 per 1000, against 22·3, the mean rate in the corresponding periods of the nine years 1876–84. The lowest rates in these towns last week were 10·5 in Derby, 13·7 in Sunderland, 14·2 in Halifax, and 14·5 in Wolverhampton. The rates in the other towns ranged upwards to 23·7 in Sheffield, 26·5 in Manchester, 28·1 in Plymouth, and 35·4 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 486 and 520 in the preceding two weeks, declined to 429 last week, a lower number than in any week since the beginning of March. These 429 deaths included 177 from measles, 102 from whooping-cough, 37 from diarrhœa, 32 from "fever" (principally enteric), 27 from small-pox, 27 from diphtheria, and 26 from scarlet fever. No death from any of these diseases was recorded during the week in Norwich, in Wolverhampton, or in Halifax; while they caused the highest death-rates in Manchester, Sheffield, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Manchester, Sheffield, and Newcastle-upon-Tyne; from whooping-cough in Oldham, Birkenhead, and Plymouth; from scarlet fever in Leicester and Sunderland; and from "fever" in Brighton and Blackburn. The 27 deaths from diphtheria in the twenty-eight towns included 17 in London, 2 in Portsmouth, and 2 in Liverpool. Small-pox caused 51 deaths in London and its outer ring of suburban districts (exclusive of 16 London residents recorded in the metropolitan asylum hospitals and camp at Darenth), 2 in Hull, 1 in Manchester, and 1 in Sheffield. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1359 and 1201 in the previous two weeks, rose again to 1221 last week; the admissions to these hospitals, which had been 282, 272, and 180 in the previous three weeks, rose again to 204 last week. The Highgate Small-pox Hospital contained 67 patients on Saturday last, 14 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 302 and 296 in the preceding two weeks, further declined to 231 last week, and were 29 below the corrected weekly average. The causes of 66, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Bradford, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Wolverhampton, Nottingham, Oldham, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 20·5 and 21·8 per 1000 in the previous two weeks, declined again last week to 20·6, but exceeded by 2·0 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·0 in Perth and 17·0 in Dundee and in Aberdeen, to 23·9 in Glasgow and 24·5 in Greenock. The 502 deaths in the eight towns included 22 which were referred to whooping-cough, 13 to measles, 13 to diarrhœa, 7 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 3 to scarlet fever, and not one to small-pox; in all 63 deaths resulted from these principal zymotic diseases, against 59 and 74 in the preceding two weeks. These 63 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 0·1 the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to whooping-cough, which had been 27 and [illegible] in the preceding two weeks, further declined last week to 22 of which 12 occurred in Glasgow, 6 in Edinburgh, 2 in Greenock, and 2 in Leith. The 13 deaths from measles showed a decline of 2 from the number in the previous week, and included 7 in Glasgow, 3 in Greenock, and 2 in Edinburgh. The 13 deaths attributed to diarrhœa were also fewer than those in the previous week, and scarcely differed from the number in the corresponding week of last year. Of the 7 deaths referred to "fever," showing an increase upon the exceptionally small number in the previous week, 4 occurred in Leith and 3 in Glasgow. The fatal cases of scarlet fever and diphtheria were considerably below the average, and showed a decline from recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 87 and 126 in the preceding two weeks, declined again to 94 last week, and were 7 below the number returned in the corresponding week of last year. The causes of 67, or more than 13 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had declined in the preceding four weeks from 35·0 to 23·1, rose again to 29·1 in the week ending June 13th. During the first ten weeks of the current quarter the death-rate in the city averaged 30·6 per 1000, the rate during the same period not exceeding 20·1 in London and 18·5 in Edinburgh. The 197 deaths in Dublin last week showed an increase of 41 upon the number in the previous week, and included 24 which were referred to the principle zymotic diseases, against numbers steadily declining from 34 to 15 in the preceding four weeks. These 24 deaths were equal to an annual rate of 3·5 per 1000, the rate from the same diseases being equal to 2·8 in London and 1·9 in Edinburgh; they included 11 from measles, 7 from "fever" (typhus, enteric, or simple), 3 from scarlet fever, 2 from whooping-cough, 1 from diarrhœa, and not one either from small-pox or diphtheria. The fatal cases of measles, whch had been 17, 13, and 9 in the preceding three weeks, were 11 last week; and the deaths from "fever" showed an increase upon the recent weekly numbers. Seven inquest cases and 10 deaths from violence were registered, considerably exceeding the numbers in any recent week. Nearly a third of the deaths were recorded in public institutions, The deaths both of infants and of elderly persons showed a marked increase upon those returned in the previous week. The causes of 25, or nearly 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-Major F. Ferguson has arrived at Cairo, sick, from the Nile.

WAR OFFICE.—Grenadier Guards: Surgeon-Major Henry J. H. Lawrence to be placed on retired pay, with the honorary rank of Brigade Surgeon.

ARMY MEDICAL STAFF.—Surgeon-Major John Kinahan, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon Richard Henry Stewart Sawyer, M.B., from half-pay, to be Surgeon, vice Robert Lesly, M.B., deceased. The undermentioned Surgeons on probation to be Surgeons:—Samuel Hickson, M.B.; Henry James Fletcher, M.B.; Sidney Herbert Lindeman; Edward Davis; Simpson Powell, M.B.; Frederick William Caton Jones, M.B.; James Meek, M.D.; Arthur Edward Morris, M.D.; Eugene Cormack, M.B.; Claudius O'Donel, M.D.; William Alexander Carte, M.B.; Arthur Ormsby Fitzgerald; Frederick Dundas Elderton; Edward Nodin Sheldrake; Robert Everard Molesworth; John William Francis Long; Charles Langford Josling; John Francis Bateson, M.B.; William Travers Swan, M.B.; Joseph Bulfin, M.B.; Robert Lockhart Ross Macleod, M.B.; James Henry Curtis; Gofton Gee Adams; James M. F. Shine, M.D.; William Bullen Day, M.B.; David Rogerson Hamilton, M.B.; Robert Geo. Thompson, M.D.; Charles T. Blackwell; Robert Ignatius Power; Charles Randolph Kilkelly, M.B.; William Henry Bean; Nicholas Charles Ferguson, M.B.; Samuel Richard Wills; Michael Leo Hearn; Stephen Lawson Deeble; Richard Harris Hall, M.D.; William Hallaran Bennett, M.B.; John Henry Greenaway; Richard George Hanley, M.B.; William Howard Bell; Gerald Cree; Samuel Cowell Philson; John Michael Nicolls, M.B.; Frederick William Henry Davie Harris.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of 1st April, 1881, Fleet-Surgeon Frederick Augustus Brice has been placed on the Retired List, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets.

The following appointments have been made:—Surgeon Alexander Gascoigne Wildey to the *Medina;* Surgeon James M'Cardie Martin to the *Duke of Wellington;* Surgeon Alexander Gordon Andrews to the *Medway;* and George R. Moore to be Surgeon and Agent at Jersey.

ARTILLERY VOLUNTEERS.—2nd Northumberland (Percy): James Henry Davidson, Gent., M.B., to be Acting Surgeon. —2nd East Riding of Yorkshire: Thomas Bowes Shaw, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—Lieut.-Colonel Commandant Pearson Robert Cresswell, F.R.C.S., commanding the 2nd Glamorgan Rifle Volunteer Corps, is granted the honorary rank of Colonel.

THE VOLUNTEER MEDICAL STAFF CORPS.—Surgeon John H. Casson, from the 2nd Derbyshire Rifle Volunteer Corps, to be Surgeon. Surgeon William Henry Platt, from the 1st Tower Hamlets Rifle Volunteer Corps (the Tower Hamlets Rifle Volunteer Brigade), to be Surgeon. The undermentioned gentlemen to be Surgeons:—John Edward Squire, M.D.; Samuel Walter Sutton, M.D.; Edgar William Willett; William Edmund St. Michael Raw.

Correspondence.

"Audi alteram partem."

THE COLLEGE ELECTION.

To the Editor of THE LANCET.

SIR,—Although I think it would be very undesirable, as a precedent, that any candidate for election to the Council of the Royal College of Surgeons should be called upon to state precisely his views upon any question, as a test of his eligibility for an office wherein he should be able to exercise an unfettered judgment, in accordance with the confidence reposed in him and in his honesty of purpose by the electoral constituency of Fellows, yet it seems to me that the present occasion is quite exceptional with regard to that principle.

Certain matters of vital consequence to the rights of the Fellows, and the future welfare, or perhaps the existence, of the College, have been so freely and fully considered, so threshed out by discussion, that it is simply impossible for any eligible candidate for the College Council not to have arrived at a definite conclusion thereon. Accordingly, I proceed to state my convictions, and the course therefore I should be prepared to take in the event of my being honoured with a seat in the Council.

There is one positive wrong which underlies all other forms of exclusiveness, and the mal-influence of which paralyses the hands of that section of the Council who are still bound by tradition—I mean the restriction of the office of examiner in surgery almost exclusively to members of Council. Other positions of emolument have been thrown more open to the Fellows and to the Members generally; but the chief source of emolument yet remains restricted to members of the Council. The injustice and the inconsistency of this exclusiveness are obvious, seeing that many Fellows may be highly qualified for the office of examiner in surgery who are not on the Council, and that members of Council may possess the capacity for administration rather than special fitness for the office of examiner. The two positions are not convertible. Let the conjunction of these two offices be broken up, and then the Council will see no desirability in their maintaining the present *status quo.* Other things would follow. Who can doubt that the President of the College should not be elected necessarily in the order of rotation from members of the Council, that at a yearly meeting the report of the Council should be submitted to the electoral constituency, and that no vital change in the constitution and relations of the College should be undertaken by the Council without the knowledge and concurrence of the Fellows and Members constituting the College? In all these respects the College should stand upon the same basis as that of any other Society—say, the

Royal Medical and Chirurgical Society, which is quite analogous in its relations to the general constituent body.

Well, these are the conclusions at which I have long since arrived after mature consideration, and to which I should be quite prepared to give effect in the Council of the College. In private circles I have freely acknowledged my convictions; and as the present crisis seems to demand a public statement of them, may I ask you to disseminate them through the medium of THE LANCET?

I am, Sir, yours obediently,
FREDERICK JAMES GANT.

Connaught-square, June 17th, 1885.

AURAL EXOSTOSES.

To the Editor of THE LANCET.

SIR,—The first case in which Mr. Field removed an aural exostosis with a dentist's drill occurred in 1877. He says he "got the idea of the operation from Dr. Matthewson's paper." This paper was read at the first Otological Congress held in New York in the autumn of 1876, and was afterwards published. My article appeared in THE LANCET of Jan. 22nd, 1876. Mr. Field says of me: "He has not published any cases *for our guidance describing the details of the operation*." But in the article referred to I mentioned that since 1874 I had used a dentist's drill to remove aural exostoses, and maintained that they arose from a local irritation of the external meatus, dismissing as quite untenable the theory of their gouty origin. I noted that I had observed as many as fourteen cases (exclusive of hospital patients) in one year. The conditions under which they should be operated upon, and, what is of equal or more importance, when they should not, are there most definitely stated. Besides this, in my article in "Holmes' System of Surgery" the pathology of these growths is discussed; the method of operating, the difficulties met with, the conditions under which they should be removed, and when not, are all most carefully described. The same may be said of the last edition of my lectures, in which five pages are devoted to the subject. In regard to the International Medical Congress, the words I actually used (and they are reported in the Transactions) were: "Another point which also bears out the theory of a local cause to these growths is one which I have constantly observed (*and it has been recorded by others*). It is that, when enlargements are found in both canals, patients have been much addicted to sea-bathing."

I am, Sir, your obedient servant,
W. B. DALBY.

London, June 13th, 1885.

*** This controversy must now end.—ED. L.

CHLOROFORM v. ETHER.

To the Editor of THE LANCET.

SIR,—I confess to a certain feeling of disappointment that my letter on this subject, which appeared in your journal of March 7th, has not produced more expressions of opinion than it has. In THE LANCET only two have appeared, but I have had sent me from the States a reprint of an article in the *Boston Medical and Surgical Journal* of April 13th, 1882, entitled "Homicides by Chloroform," which in its condemnation of this drug goes further than Messrs. Braine and Buxton. Mr. Braine, after quoting my contention "that in the production of complete anæsthesia there is little or no difference (in danger to life) between chloroform and ether, whilst in the after-effects, especially as regards vomiting, nausea, and depression of spirits, chloroform is much superior to ether," and saying that this is exactly contrary to what he has been endeavouring for years to demonstrate, begs to point out to me that whilst ether is a cardiac stimulant, chloroform, on the other hand, is a depressant of the heart's action; that the former never kills by paralysing the heart, whilst, on the contrary, the principal cause of death in fatal chloroform cases is the sudden cessation of the heart's action.

Now, is not this too bad? I write a letter in which it is manifest that I take for granted that chloroform kills by depressing the heart's action, and show how this can be remedied, and then am addressed in the *du haut en bas* fashion of "May I point out," &c. I may say further that when I first began giving chloroform, now some twenty-four years ago, I unconsciously came to the conclusion that the heart is the organ on which it tells first, for I found myself always keeping one hand on the pulse whilst giving chloroform with the other, long before I had formulated the opinion in so many words. Next, he acknowledges that dangerous symptoms occasionally arise during the administration of ether; but when these do occur the respiratory organs are affected, and there is plenty of time for the proper application of remedies, these symptoms being rarely followed by death. Surely this is begging the whole question, to elucidate which my letter was written. Are these symptoms rarely followed by death? Let us see. Mr. Braine asks me to consult the statistics of fatal cases, in which I shall find that the proportion of deaths under the administration of chloroform is about 1 in 4500, whilst that under ether is only 1 in 20,000! Where are these statistics? I challenge them at once as false and absurd. I have seen, I believe, at least 10,000 cases of chloroform administration with only one death, and that in a woman who, as we found afterwards, had been drinking heavily for a fortnight. But I have got some statistics, compiled for the Registrar-General, who has kindly furnished me with them. I asked for a return of the deaths from the various anæsthetics for the past ten years, but was informed that they could not be given separately; however, a return of the deaths from chloroform and ether (1874-83), in which probably are included those from other anæsthetics in England and Wales, was sent.

Before giving this, let us consider how stand matters bearing on these statistics. First of all, population has increased, but not in so great a degree as to affect materially the comparatively small number of deaths from these drugs. Secondly, there are many operations done now, or done in greater number than were done formerly; but, on the other hand, there are many operations done now without anæsthesia which formerly were done nearly always with it—such as for cataract, &c. I speak of the days before the introduction of cocaine, and without any reference to it whatever. Thirdly, I believe that there is more care bestowed upon the administration of anæsthetics than formerly; and, fourthly, if what the advocates of ether say is true, there is much greater safety in this drug.

From the first three of these considerations we may fairly draw the conclusion that we ought to expect only a slight increase of deaths owing to the increase of population, the other causes balancing each other, but when we add the fourth, we ought to find a great decrease indeed. Mr. Braine says ether is 4444 times as safe as chloroform! Now what are the facts? In 1882, when ether was much used, the deaths of men from chloroform and ether were more than twice as great as in 1874, when ether was scarcely used at all. In women in 1882 there were exactly 75 per cent. more deaths than in 1874. In the second half of the decade, in both sexes, the numbers are 150, as against 101 in the first half.

Ought not these facts to make us pause before we assume that there is the much vaunted safety in ether? Is it not the fact that all anæsthetics universally used are equally fatal, for you cannot abolish all the outward manifestations of life, save those of respiration and circulation, without coming perilously near to the extinction of these. By "equally fatal," I mean this: that if one anæsthetic were used exclusively for all cases through a certain period of time, and another anæsthetic were used exclusively for all cases through another like period of time, the rate of mortality would be the same in each.

I am told by a friend on whom I can rely implicitly that in a ten years' connexion with a large hospital there have been two deaths from anæsthetics, of which one was from chloroform and one from ether. I believe that during the past year, in the United Kingdom the deaths from chloroform and ether have been about equal.

So far I have confined myself to Mr. Braine's letter, inasmuch as the "safety" point is the principal one. As to the other letter, as Mr. Buxton agrees with Mr. Braine, I *need not enter further into this point, nor need I dilate much* on the sequelæ point, as Mr. Buxton agrees with me in considering that the after-effects of ether are far worse than those of chloroform. I think few doubt this. When the ether wave came from the West I made an experiment on myself, and in consequence obtained an accurate idea of what I should think must be the prodromata of suicide. Later, when I tried the drug on patients, I found that whilst the symptoms preliminary to complete anæsthesia were no less terrifying than those of chloroform, the symptoms succeeding were far worse and more prolonged. One old gentleman on whom I operated for cataract had a profound melancholy for several months, which he attributed to ether; and I was repeatedly asked by the matron of St. Paul's Eye and Ear Hospital not to give ether, as the patients were so much more sick and ill, and longer in recovery.

Since writing the above I have received from the Registrar-General a return of the deaths from chloroform and ether—practically of chloroform alone—for the ten years 1864–1873. The numbers are: males 106, females 24, total 130. The lowest year was 1866, with 4 males to 1 female; the highest year was 1872, with 19 males to 4 females.

The following is the copy of the Report furnished me by the Registrar-General.

"England and Wales.

'*Deaths from Chloroform and from Ether registered in England and Wales in each of the years 1874 to 1883.*

Year.	Males.	Females.	Persons.
1874	*13*	*6*	19
1875	16	5	21
1876	*20*	*6*	26
1877	12	7	19
1878	*13*	*6*	19
1879	14	9	23
1880	*17*	*9*	26
1881	24	7	31
1882	*27*	*10*	37
1883	24	9	33
Total in the 10 years	180	74	254"

I am, Sir, your obedient servant,

Liverpool, May 5th, 1885. Geo. E. Walker, F.R.C.S.

A DANGER FROM DRAIN VENTILATION.

To the Editor of The Lancet.

Sir,—Not long ago, when attending a young lady with ulcerated throat, I heard of a family several members of which were for a long time ill with troublesome ulceration of the throat, the cause of which was for a time a mystery. It was at last found out that the ventilating pipes in connexion with the drains of an adjoining building were not carried up above the roof, the result of this arrangement being that sewer gas found its way into the dwelling of the patients by the upper windows. Now, when so much is being done in the way of drain ventilation, it becomes obviously a most important matter for the ventilating shafts to be carried well above all windows that may be in proximity. In the heavy air of a town it is especially important to let the gas escape at an altitude where there is some air current to blow it away.

I am, Sir, yours obediently,

Welbeck-street, W., June, 1885. John C. Thorowgood.

COCAINISATION OF THE BLADDER.

To the Editor of The Lancet.

Sir,—I see that you refer in your issue of May 30th to an interesting case of litholapaxy, rendered painless by the injection of cocaine into the bladder, the operation being performed by Professor Bruns. Permit me to point out that the complete anæsthesia induced in this case is not obtainable in all. From the startling success of the first cocaine litholapaxy, performed at St. Peter's Hospital for Stone soon after the introduction of the drug, it was expected that cocaine would partially supersede the ordinary anæsthetic in operations upon the vesico-urethral tract. Subsequent experience, however, has clearly shown that it cannot always be relied upon to produce anæsthesia. I would quote two cases illustrating the extremes.

A. S——, aged nineteen, had suffered from difficulty in micturition for twelve years. Passed blood at onset of symptoms; none since. Had been treated for the last three years for gleet. Applied at the out-patient department at St. Peter's in January; stone detected. Eight grammes of a 4 per cent. solution of cocaine were injected into the bladder, and the stone crushed and evacuated without pain. The stone weighed fifteen grains.

D. G——, aged forty-five, had suffered for two years from stone, classical symptoms being present. Sixteen grammes of a 7 per cent. solution were injected. On attempting to crush the stone much pain was experienced, and the operation had to be completed under ether. The stone weighed eighty-five grains.

Upon what does this resistance to the action of the drug depend? Deficient knowledge of its properties, probable sources of error in its application, great chances of adulteration, and all combine to prevent a correct answer being given. A careful consideration of unequivocal cases of cocaine resistance will prove of great value, for I do not doubt that a thorough microscopical examination of the pathological condition of such will afford a clue to some of the many, and at present inexplicable, neuroses of mucous membranes.

I am, Sir, yours truly,

E. Hurry Fenwick, F.R.C.S.

George-street, Hanover-square, W., June, 1885.

LUNACY AMENDMENT ACT.

To the Editor of The Lancet.

Sir,—The workhouse medical officers appear to me not to have awakened to the serious manner in which their interests are threatened by the above Bill. In the first place, they will, in country places, be subjected to great *inconvenience by the disqualification of officiating clergymen*, as a magistrate is not to be found always within a reasonable distance, and, when found, his superior *intelligence* is not always to be reckoned upon. It appears to me that this clause is instigated by the judicial mind, which is unable to free itself from the old-fashioned idea that lunacy is in some sort a crime, and should be dealt with by a justice.

By the amendments of May 13th it is provided that "an alleged lunatic *may* be *received into a* workhouse and detained for not more than forty-eight hours." This ought to be three *days, for obvious reasons*: very many cases cannot be decided upon at one interview; often friends should be *communicated* with, *facts ascertained* and verified; and when a Sunday intervenes the relieving officer and magistrate cannot be communicated with and distances traversed all within the short period of forty-eight hours.

Clause 10, subsections 4 and 5, provides that "no person shall be detained in a workhouse for more *than fourteen* days without *an order* under the hand of a justice; and this order must be made on the *application* of a relieving officer *supported* by a medical certificate in Form 6 under the hand of a duly qualified medical practitioner, *not being an officer of the workhouse*, and by a certificate under the hand of the medical *officer of* the workhouse in the Form of the schedule." This is followed by a penal clause imposing a fine *not* exceeding £10 on the medical officer for every day, or part of a day, during which he omits to perform the preceding duties.

Now, as some medical officers have entertained doubts as to the purport of the above—and I have read the Act through with a solicitor, a barrister, and a stipendiary magistrate,—I give its meaning and effect. A medical officer will not have the power to detain any lunatic in the workhouse without sending the case before a magistrate and another medical man with a certificate from himself. This being imposed upon him as part of his duty as workhouse medical officer, he will not be able to claim any *payment* for it; this is confirmed by a clause in the amendments of May 13th which runs thus: "The *guardians of the union* to which the workhouse belongs shall pay such *reasonable remuneration* as they think fit to *the medical practitioner* who, not being an officer of the workhouse, examines a *person* under this section." *Thus, it is* beyond all doubt that the workhouse medical officer, having had the trouble *and* care of the case, *is defrauded of* a fee and placed in a subordinate insulting position. It will also be harsh and injurious *to the unfortunate* lunatic, as the medical officer will not be able, as he is now, to grant permission to the friends *to take the patient* out for a few days' holiday, and readmit the case without further trouble; but after it is *decided upon by the magistrate* and the outside doctor, he or she will be virtually a perpetual prisoner in the workhouse.

Every one of the 17,330 cases now in the workhouses must, within fourteen days of the passing of the Act, be proceeded with under Clause 10; that is, the unfortunate medical officer must fill up a form of notice to the relieving officer and a certificate according to Form C in each case, and without any payment.

I am, Sir, yours faithfully,

June, 1885. THOMAS J. VALLANCE, M.D., F.R.C.S.Exam.

THE TITLE OF "DOCTOR" FOR LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to correct one or two impressions which my letter of the 30th ult. seems to have conveyed to Mr. Rayne? In his letter of the 6th inst., Mr. Rayne takes exception to the terms "*considerable extra expense*" which I said was incurred by those who, like myself, had taken a university degree *in addition to the membership of the Royal College of Surgeons*, and he further informs me that this "extra cost exists only" in my "imagination." How this can be the case I cannot understand, as surely, when a man first goes through the full four years' curriculum at one of "the great London schools" (in my case at Guy's), *takes the M.R.C.S., and the L.R.C.P. or L.S.A.* in London, and then, in addition to this, spends two more years in Aberdeen, having to pay for board and lodging, additional courses of lectures, dissections, practical courses, and for examination fees, this naturally entails considerable extra expense.

With regard to the "easy curriculum" which leads to Scotch graduation I do not think that those conversant with these examinations will agree with this statement; the experience of myself and of most of those from London schools who were in Aberdeen during my time proved the contrary. I only refer to those who like myself had already passed the College of Surgeons in London and some who, in addition, had also the L.R.C.P. Lond. or L.S.A.

Mr. Rayne refers to "*men like Mr. Wright and his compeers who have experienced so comparatively easy a curriculum.*" Not having the honour of knowing him, I am unable to form so ready a judgment as to the curriculum of "men like Mr. Rayne and his compeers," though I believe the curriculum of one London hospital is much the same as that of another.

I fully agree with Mr. Rayne that something should be done to protect the London students from being in any way overshadowed by the licentiates of the Scotch corporations; I pointed this out in my first letter, and I suppose no one doubts that "the student at the great London schools has unrivalled opportunities for clinical and surgical work;" but from personal experience of the "teaching" both in Aberdeen and London, the former certainly holds its own, and this is the opinion of many more able to judge than I was, and certainly more fit to do so than Mr. Rayne, who has not experienced it.—I am, Sir, yours faithfully,

C. ST. JOHN WRIGHT, M.B. Aberd., &c.

St. Mary's Infirmary, Islington, June, 1885.

LIVERPOOL.

(*From our own Correspondent.*)

CITY IMPROVEMENTS.

It has been proposed to spend £100,000 in city improvements, and in furtherance of this an inquiry was held on the 16th inst. at the Town Hall before Major Phipps Carey, [illegible] inspector appointed by the Local Government Board to receive evidence. The Town Clerk, in opening the case, quoted the resolution passed by the City Council on April 15th last, which was as follows:—"That [illegible] £100,000 be borrowed under the provisional order [illegible] 1884, confirmed by the Local Government Board's [illegible] Orders Confirmation Act, 1884; and that application [illegible] the requisite sanction of the Local Government Board." Dr. Stopford Taylor, the medical officer of health, [illegible] his evidence said that under the original [illegible] presentments were made dealing with 620 houses, 615 [illegible] and 20 partly demolished. Under [illegible] Act of 1882, 532 houses were reported. In 1884, [illegible] demolished; and in 1884 he reported 336 houses, which the Council referred to the Insanitary Property Committee to be dealt with; 391 houses, which were referred to the clerk of the peace, and were brought to the notice of the grand jury, made the seventh presentment; and 734 houses which were similarly referred became the eighth presentment. The number of houses that he estimated required to be still dealt with was near upon 10,000, which, taking the low figure of five inmates to each house, would make a displacement of something like 50,000 people. This must, in order to meet the requirements of business and the comforts of the people themselves, be spread over a lengthened period. After hearing all the evidence, the inspector promised to report to the Local Government Board.

NEW MEDICAL MAGISTRATES.

Mr. Charles White and Dr. John Hankinson Gornall, both of Warrington, have been placed on the commission of the peace for that borough. Dr. Gornall is medical officer of health for Warrington, and was a distinguished student of the Liverpool School of Medicine more than twenty years ago.

THE HEAT AND SUNSTROKE.

From being comparatively cold it became intensely hot last week, the increase of temperature being remarkably sudden. On Saturday, a man while loading a cart was seized with what was believed to be sunstroke, and removed in the ambulance to the Northern Hospital, where he was pronounced by Dr. Fisher, one of the resident staff, to be in a very critical condition.

MORE "CANNIBALISM."

In spite of severe sentences, the disgusting offence of biting still continues to be frequently practised here. In two recent cases the victims were city constables, and in each case the assailant was awarded three months' imprisonment with hard labour. In a recent case, the prisoner, a young woman, was committed to the sessions for trial for biting severely another woman, whom she also dragged to the ground and beat.

MEDICAL PRACTITIONERS AND LIFE INSURANCE.

From time to time most heartrending cases occur of the widows and orphans of deceased medical practitioners being left very slenderly if not totally unprovided for, rendering necessary appeals to the generosity of their medical brethren. In most of these cases there has not been any life assurance effected, or the policy has been allowed to lapse. With every disposition to be generous, it is felt by many practitioners, especially the younger ones, that these appeals come hardly upon those who are striving by prudence and thrift to avoid falling into similar errors. The proverbial uncertainty of any individual life applies particularly to busy medical practitioners, and a more general adoption of assurance, against accident as well as death, would go far towards making a provision to many an otherwise destitute widow and orphan.

Liverpool, June 17th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

CHOLERA PRECAUTIONS IN THE NORTH.

THE prevalence of cholera in Spain has caused no little anxiety to our authorities, for the Tyne is in direct communication in the way of commerce with Spanish ports. It is satisfactory to know that the Local Government inspector the other day expressed himself as being well satisfied with the steps that have been taken by our sanitary authorities to deal promptly with any case occurring in Tyne-bound vessels. At the meeting of the Tyne Sanitary Authority last week, however, our medical officer of health, Mr. H. E. Armstrong, stated that a rather singular procedure was sanctioned by the authorities at a neighbouring port, Seaham Harbour, which is also in constant communication with Spain [illegible] directions were given that any vessel approaching the harbour with infection was not allowed to enter, but was to be warned off. Our medical officer of health very properly stated that this was a singular and very objectionable way of meeting infection, and it was in fact unfair to shift danger, as it were, from your own to your neighbour's door. It appears, however, that the port in question is private property, and as such has rights not possessed by an open harbour; yet surely, in a case of this nature, if property has its rights, it also has its duties.

DR. DAVID DRUMMOND.

Dr. David Drummond, one of our lecturers, and a physician to the infirmary, who had, to the great regret of his many professional friends, the misfortune to be laid aside from work for several weeks, suffering rather severely from some accidental septic absorption, has now, I am happy to say, quite recovered, and has in consequence resumed his hospital and general duties. Some other cases, although not so severe, have been noticed here of late, giving rise to the view that there must be at times some peculiar tendency to this affection, so full of peril to practitioners, and which so often occurs at what may be termed the "fag end" of the session.

POISONING BY NITRATE OF LEAD AT SUNDERLAND.

An inquest was held last week at Sunderland upon a German captain, who died rather suddenly at sea off Sunderland. It appeared from the evidence that the deceased, not feeling well, had taken some medicine supposed to be Epsom salts, which immediately gave rise to vomiting and purging, with collapse, ending in death. On analysis, it was found that the unfortunate captain had taken in mistake nitrate of lead, and a verdict was returned in accordance with the circumstance.

THE SURGEON TO DURHAM GAOL.

At the conclusion of an inquest held on a late prisoner last week in Durham Gaol, the coroner took the opportunity of paying a graceful tribute to Dr. Boyd, the prison surgeon, who is now retiring. The coroner stated it was the last occasion on which they would have Dr. Boyd's services, and he referred to the great assistance he always had from that gentleman. "He had now been prison surgeon for sixteen years, and never at any time had they the slightest difficulty or doubt with respect to the evidence that the Doctor had given with regard to the nature or treatment of the cases coming before them in that prison, and he hoped the Doctor would retain that good health in the future which he had enjoyed in the past." Dr. Boyd feelingly replied in a few well-chosen words to the compliments of the coroner.

MEASLES AT JARROW.

The subject of payment to practitioners at Jarrow for certifying measles came up for consideration by the Jarrow authorities last week. This town, as I have told you, has suffered very severely from measles, and in consequence the profession was asked to certify cases to the medical officer of health. The disease lately abating, exception was taken to the cost of certificates, which were stated to be useless; but, on the other hand, the medical officer of health (Dr. A. C. Munro), while admitting the great difficulty of isolation in workmen's houses, pointed out that in every case certified disinfectants had been used, and with marked results, the disease now subsiding, no doubt to some extent owing to these precautions.

UNIVERSITY OF DURHAM.

The Easter term examinations for degrees in connexion with the Newcastle College of Medicine affiliated to the University of Durham commenced yesterday in the Assembly Rooms, Newcastle-on-Tyne, the existing Medical College being inadequate for the purpose. Upwards of fifty candidates came forward, the largest number ever presented for the final degree in the history of the College.

Newcastle-on-Tyne, June 17th.

EDINBURGH.

(*From our own Correspondent.*)

THE LATE PROFESSOR FLEEMING JENKIN, LL.D., F.R.S.

LITERARY and scientific circles in Edinburgh have sustained a heavy loss in the sudden death of Professor Fleeming Jenkin. He had been in delicate health for some months, but was much restored by a holiday in the south of England, where he left Mrs. Jenkin when he came to Edinburgh a few days ago to undergo an operation for the radical cure of varix. All went well after the operation till towards the end of the second day, when symptoms of septic absorption made their appearance. Still his condition was not considered dangerous; and it was not till the early morning of the third day that any serious mischance was apprehended. On that morning, however, a rapid aggravation of the symptoms occurred, and at noon he succumbed to the virulence of the septicæmic attack. On Monday night the remains were removed by rail to Stowting Court in Kent, the family seat, where the funeral arrangements were subsequently carried out. His death has caused universal regret in Edinburgh, where he was highly esteemed in his public capacities, and much loved in the large social circle in which he moved. Professor Jenkin was a man of true genius, and scarcely any branch of science, natural or mechanical, has failed to profit largely by the results of his labours. In sanitary science this was pre-eminently the case; for here, in addition to the large number of technical modifications and improvements which are associated with his name, his energy is illustrated by the strenuous way in which he urged the claims of sanitation upon communities at large; and it was as an outcome of two lectures on this subject, afterwards published under the title of "Healthy Houses," that the Edinburgh Sanitary Protection Association was formed; an institution which has proved a great boon to this city, and to several others where its working principle has been reproduced.

UNIVERSITY FINAL MEDICAL EXAMINATION.

The final examination for the degrees of M.B. and C.M. will take place on Monday and Tuesday, June 22nd and 23rd. The candidates' names on the list amount to over 240, a larger number than have appeared for examination here in any recent year.

ROYAL EDINBURGH ASYLUM.

The annual report of the Edinburgh Asylum has just been published, and is well worthy of perusal. In the portion contributed by the Physician-Superintendent, Dr. Clouston records the results of the year's work, illustrating them by notes of cases of special interest. His report contains also several valuable suggestions for improvement, amongst others advocating that incurable pauper lunatics who are easily managed should be kept in the hospital wards of the poorhouses with suitable nursing, instead of overcrowding the wards of the asylums as at present is the case, and masking their true character of hospitals for the cure of the curable insane.

Edinburgh, June 16th.

IRELAND.

(*From our own Correspondent.*)

THE Council of the Royal College of Surgeons will this week elect a second examiner in the departments of physics, chemistry, and medical jurisprudence.

CORK SOUTH INFIRMARY.

In a recent number (p. 1015) I drew attention to the dispute which existed between the trustees and the profession generally in Cork as regarded the election of the medical staff for a period of only five years, when a re-election became necessary. On the 12th inst. a meeting of the trustees took place, to elect for a period of five years, as required by Rule 1, several members of the medical staff. One of the trustees spoke in high terms of the services performed by the medical officers, and proposed the following resolution, which was carried unanimously:—"This meeting of the trustees of the Cork South Charitable Infirmary and County Hospital desire to express their regret that the medical and surgical staff of this hospital, as also a large number of the medical profession in the city of Cork, should have taken offence where none was intended at the advertisement issued by the trustees in order to carry into effect Rule 1." Drs. Curtis, E. R. Townsend, C. K. D. Tanner, and H. R. Townsend were then re-elected to their respective appointments without opposition.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

In the forty-third annual report of this Society the committee express their regret that the number of subscribers to the fund remains so limited that the grants in most instances are far below the requirements of the cases. During the past year £1272 was distributed, leaving a balance of upwards of £200 to meet the working expenses. Of the amount distributed £215 was to medical men, £973 to widows, and £34 to orphans. It is satisfactory to learn that an increase has taken place in the amount collected from the students in some of the hospitals and schools, and the committee trust that the other institutions may be encouraged to do something to bring students more into sympathy with the Society than heretofore. Dr. Cruise, in moving the adoption of the report at the recent annual meeting, referred to the apathy of a large number of the profession with regard to assisting the Society. As he very properly pointed out, it was the poorer members of the profession who would require the assistance of the Society, and they therefore ought to subscribe, no matter how small the sum. I may add that the poorer members will *not* subscribe, and their indifference to their own interests is followed by a considerable section of practitioners who decline to help those who refuse to help themselves.

A GRIEVANCE.

A matter of importance to dispensary medical officers was recently drawn attention to by the Council of the Irish Medical Association at their annual meeting. It appears that until recently medical practitioners when called to attend persons in custody of the police applied to the Under Secretary at Dublin Castle for their fees, which were promptly paid. Lately, however, the Lords of the Treasury decided that to avoid these fees the police officers should procure tickets, when necessary, so as to obtain the services of the dispensary medical officers. In several instances, owing to the urgent nature of the cases and the difficulty or delay in procuring tickets, the police called in dispensary medical officers, who claimed the fees as heretofore, but were refused them on the ground that "in urgent cases the dispensary medical officer was bound to give his services gratuitously pending the procurement of a ticket." The attention of the Treasury Remembrancer for Ireland was directed to the regulations of the Local Government Board, which define the duties of dispensary medical officers, in the hope that the fees claimed would be paid, but that official upheld the course recently adopted, so that the matter will have to be decided in a court of law.

Dublin, June 15th.

PARIS.

(*From our Paris Correspondent.*)

CONVICTION OF PEL FOR POISONING BY ARSENIC.

THE clockmaker, Pel, whose case I reported in THE LANCET of Jan. 31st, and again in that of April 11th, appeared before the Court of Assizes of the Seine on Thursday, Friday, and Saturday last, on two specific charges brought against him—viz., for having, in the first instance, poisoned his first wife, Eugénie Buffereau, in 1880; and secondly, making away with his servant, Eliza Bœhmer, with whom he was on intimate relations. The trial was most perplexing, owing to the mysterious demeanour of the accused, for throughout it he never betrayed the slightest emotion, nor could the Court obtain any notice from him as to his guilt either by word or deed, for he could hardly have been more impassive if he were witnessing the trial of another person for whom he had no concern whatever. After having weighed the evidence on both sides, the jury returned a verdict of guilty of the second charge only—viz., the poisoning of Eliza Bœhmer—and the accused man was condemned to death. It is not for me to plead the cause of this unfortunate culprit, but I cannot refrain from remarking that the man evidently acted under some morbid (psychopathic) influence, and that he appeared irresponsible for the series of murders he is believed to have committed, for he was always an eccentric character, and it was stated in the preliminary act of accusation that in 1877 his conduct was such as to necessitate his being removed to the Ste. Anne Lunatic Asylum, where he remained five weeks, and yet, strange to say, no allusion whatever was made to this circumstance in the defence.

PROFESSOR GERMAIN SÉE ON ASTHMA.

According to Professor Germain Sée, the only curative means against nervo-pulmonary asthma is "iodo-therapy"—that is, ioduration of the lungs and of the nervous respiratory system. But this method is not always tolerated, and patients are often induced to resort to the empirical remedies in vogue, all based on the combustion of certain substances and the inhalation of vapours thus produced. These vapours always contain a special substance to which the name of "pyridine" has been given. This substance is met with in all the products of the dry distillation of organic matters, of coal tar, of the principal alkaloids, in the fumes of tobacco, in nicotine, and in the animal oil of Dippel, from which it is ordinarily extracted. It is a colourless liquid, very volatile, of a strong penetrating odour, miscible with water in all proportions, forming, with mineral acids, soluble bases, but unstable. Professor Sée endeavoured to determine, experimentally, the physiological effects on patients suffering from asthma and from disease of the heart. The following are the conclusions of his work on the subject, which he lately presented to the Academy of Sciences:—1. Whatever the form or origin of asthma, ioduration constitutes the veritable curative method. When iodism intervenes, pyridine should be resorted to, but only during the fits. It is the best palliative, whereas iodine is the most efficacious remedy. 2. Pyridine is superior to the injection of morphine; its action is more durable and much more inoffensive. 3. In simple nervo-pulmonary asthma the fits cease completely. When the asthma is complicated with permanent pulmonary lesions, the duration of the treatment should be continued beyond eight or ten days to ensure relief. In cardiac asthma, with or without renal and dropsical complications, pyridine would render the greatest service in combating the most persistent and painful of the phenomena which accompany heart disease. The best mode of administering pyridine consists in pouring four or five grammes on to a plate, which is placed in a closed room, containing about twenty-five cubic metres of air. The patient, placed in a corner of the room, breathes the air impregnated with the vapours of pyridine. This treatment should be repeated for about twenty minutes three times a day. The absorption is immediate, and the pyridine can at once be detected in the urine.

Dr. Gibier has been charged by the Minister of Commerce to proceed to Spain to study the cholera, and the method of "cholerisation" practised by Dr. Ferrán of Valencia.

Paris, June 16th.

THE CHOLERA IN VALENCIA.

(*From our Special Correspondent.*)

THE great question at the present moment agitating all Valencia, if not a great part of Spain, is that of Dr. Ferrán and his experiments in inoculation for cholera—the disease which has now fairly got hold of this fair province. In the train, in the streets, the stranger is struck by the frequent mention of the words "cholera" and "Ferrán." Dr. Ferrán is a native of Tortosa; he is about thirty-six years of age, and received his medical education at Barcelona, where he obtained a special prize for his essay on Microbiology, and numerous other prizes connected with professional subjects. During the great cholera outbreak last year in Marseilles, he was sent as special commissioner from Barcelona to study the disease, which was then raging. There he spent three months at the Faro Hospital, enjoying the advantage of frequent communication with the celebrated Dr. Koch. On his return to Valencia he devoted much thought and study to the subject, and on the appearance of cholera in this province in March, he commenced a series of inoculations, first at Tatira, and next at Alcira, where he soon began to exercise a powerful influence. His system may be briefly described as follows: Regarding himself as following in the legitimate train of Koch and Van Ermengem, he considers the comma bacillus of Koch as only one stage of the micro-organism; he (Ferrán) declares that it passes through several, and, utilising his micro-organism as finally developed by him, he injects it (suspended in a medium, such as chicken broth or beef-tea) into the human being, and so ensures the individual against an attack of cholera, or, at all events, if attacked at all, a very mild one will ensue. On arriving at this town some days back, I at once proceeded to see Dr. Ferrán, and found him at home, with two assistants, busily engaged in inoculating various people. There were quite fifty done whilst I was there, of all ages and sexes. The operation is a very simple one. About half a cubic centimetre of the fluid containing the micro-organisms is placed in a small hypodermic syringe and injected into the back of the arm about four inches above the elbow. It is usually done in both arms. Many of those present would only be done by Dr. Ferrán himself, having a kind of superstitious faith in him only. I was told that in about six hours the constitutional symptoms set in, and lasted from four to as many as forty-eight hours, the violence of the symptoms varying in different individuals. I called the same evening at the house of a newspaper editor, who, with three of his family, I had seen inoculated in the afternoon, and found only one of them complaining of any unusual symptoms; but his brother, who lived close by, was taken so seriously ill as to be alarmed, and sent for his medical adviser; however, he eventually regained his normal state of health. On asking Dr. Ferrán if in all his inoculations, now some thousands, he had seen or heard of anyone having suffered ill effects, either constitutionally or locally, he declared most emphatically, "No." He subsequently showed me over his laboratory, his preparations and cultivations in their various stages under the microscope, and about 100 bottles containing his redoubtable micro-organisms. He favourably impresses one in conversation when explaining his views and ideas. He is a quiet, gentlemanly, and I should say very self-reliant man, and gave me the idea of one who is much worried, and to whom a period of rest would be an intense boon. He showed me letters he had received from many distinguished men in Europe encouraging him in his work, and seemed particularly anxious that the English Government would institute an extended inquiry into the whole matter.

The Royal Commission of Spain is at present here and in the neighbourhood investigating Dr. Ferrán's method and the epidemic on behalf of the Government. The president is Dr. Alonso Rubio, of the Royal Household; the other members are Dr. Mendoza, a chemical professor in Madrid University, and Professors Maestre San Juan and Dios Benitez, with Señor Castellote as secretary. Events in Spain move slowly, and the Commission moves slowly, and when its report will see the light it is hopeless to speculate, and whether it will be of any value when it does see the light is a very moot question, as things in Spain, and more particularly this epidemic of cholera, are so mixed up with private interests and political movements that it will lose much of its value from a scientific point of view. Ferrán's disciples have already secured a strong partisan in the eloquent Castelar, whose republican proclivities are so well known, and whose support may injure their cause more than anything else. There is also a Portuguese Commission here of three members from Lisbon, Coimbra, and Oporto respectively, highly intelligent and scientific gentlemen, and from them I expect much useful and trustworthy information on the subject, as they are well qualified to deal with it and will be totally free from all local and political prejudices. So far they are very reticent, and beyond the usual Continental shrug nothing is to be got out of them. There is also a delegate from Brazil, and a representative from the Parisian paper *Le Temps*, besides hosts of local celebrities.

With regard to the cholera itself, so far as a painful Indian experience will allow me to judge, it is undoubtedly Asiatic, and of a virulent type. Last evening I went out to the cholera hospital, and saw many cases with the medical man in charge. There were about twelve women and seven men; the former seemed much the worse cases, three of them were then *in extremis*, and one, a young girl, had only been brought in at eleven o'clock in the morning. They seemed well cared for; the good sisters glided quietly about and anticipated every wish of the poor sufferers. There was an abundance of medicines and disinfectants. The doctor appeared to be well up to his work, showed no nervousness, and, a very unusual thing in Spain, was a good linguist, speaking both French and English. The building is situated about two miles from the town of Valencia, in a poor quarter. When first established the officials had to run the gauntlet of storming, and some were seriously injured—so annoyed were the people at having a pest-house established in their midst. But now they are becoming more reconciled. With regard to Dr. Ferrán's statistics, which have already been published in several English newspapers, they read well; but I may as well state, on the authority of several Englishmen long resident in Spain, that statistics in this country are utterly worthless, and can be made and twisted so as to suit any purpose. With reference to the actual value of Dr. Ferrán's inoculation, its one established value up to the present is that amongst the credulous and ignorant it has done much to allay panic. In Alcira especially the populace have in him the most absolute faith; but with an enthusiastic and fickle race like the Valencians, the man who is their idol to-day might be stoned to-morrow. It is right also to state that, on the authority of Dr. Jelly—an English physician whose word is unimpeachable—some very sad effects in the shape of phlegmonous ulcers and blood-poisoning have resulted to several of those who have been inoculated. Into the scientific aspects of the question I have not entered. Should any good result to medical science (which I very much doubt), it will take a long time, much research, and a careful table of statistics, which I fear are not to be obtained in Spain, before anything worth placing before the English public can be obtained, and I will close this letter by stating that I have endeavoured to give a plain and simple and unbiased narrative of what I actually saw, or heard from authorities who can be thoroughly depended on.

Obituary.

JOHN THORBURN, M.D., F.R.C.P.

Dr. Thorburn died at his residence, Moss House, Rusholme, Manchester, on May 26th, after an illness of ten days. He was attended by Dr. Dreschfeld and other friends with unremitting care, though the nature of his illness, pulmonary embolism, gave almost no hope of recovery. Dr. Thorburn was born at Huddersfield in 1834, his parents afterwards removing to Manchester. Educated at the Edinburgh High School, he entered the Edinburgh University in 1849, and graduated there as Doctor of Medicine in 1855. His graduation thesis on Surgical Fever was awarded the mark of distinguished merit. At an early stage of his career as a student he was elected President of the Royal Medical Society. After taking his degree he held the posts of house-surgeon and house-physician in the Edinburgh Royal Infirmary, and house-surgeon to the Royal Maternity Hospital. Among his friends and colleagues were Sir Joseph Lister and Dr. Wilson Fox, and he had the good fortune to number among his teachers Alison, Christison, Syme, Goodsir, Hughes Bennett, and Sir James Simpson.

After leaving Edinburgh he was for some time resident assistant in the Brompton Hospital for Diseases of the Chest. Thus, thoroughly equipped, he settled in Manchester in 1858. His first public appointment was that of medical officer to the Chorlton Dispensary. In 1860 he was elected to the staff of the Clinical Hospital. Dr. Thorburn's energy and ability were soon manifested in the active part which he took, along with Dr. Henry Simpson and others, in the founding of the Southern Hospital for Diseases of Women and Children in 1866. Here he obtained opportunities for work in that department of medical science to which he thenceforward more especially devoted his attention; while the charity has owed no small share of its success to his ability and tact. In 1873 he was appointed obstetric physician to the Royal Infirmary, being the first to hold that appointment. In the same year he commenced his duties as Lecturer on Midwifery in the Royal Medical School. The amalgamation of the Royal School of Medicine with Owens College, and the subsequent constitution of the Victoria University, were attended almost as a matter of course with the appointment of Dr. Thorburn to the chair of obstetric medicine. His teaching was distinguished by the characteristics pervading all his work, clearness combined with moderation and justness of judgment.

In 1878 he took the diploma of Member of the College of Physicians of London, and in the beginning of May of this year was elected a Fellow. Throughout his long and successful career, Dr. Thorburn found time to show his interest in all progressive medical movements, and in matters affecting the physical well being of the community. He acted as secretary for three years of the Medical Society, and was subsequently elected president. He was also president of the Medico-Ethical Association. Of the Manchester Edinburgh University Society he has been annually elected president since its foundation. His interest in the public welfare is shown in his pamphlets on "The Mode of Admission to our Medical Charities," and in his little work "On Vaccination" for general readers. Amongst other short papers written by him we may mention "The Power and Place of Art in the Treatment of Disease," pregnant as it is with valuable advice to the young practitioner, "Suggestions as to the Medicinal Treatment of the Unborn Child," and his thoughtful essay on "Female Education in its Physiological Aspect." Dr. Thorburn took an active share in the foundation of the *Medical Chronicle*, and the measure of success which it has attained is in no small degree due to his efforts. For the last two years Dr. Thorburn was engaged in the preparation of a "Practical Treatise on the Diseases of Women."

To the additional strain thus imposed on one fully occupied in other pursuits, there is but little doubt that we must attribute his untimely death at the early age of fifty-one, just when he was beginning to reap the full reward of an honoured and honourable career. To all who knew his genial and kindly disposition and the straightforward manliness of his character, his death has brought a sense of personal loss. Dr. Thorburn leaves a wife and five children, of whom one, Dr. William Thorburn, is a member of the profession which his father adorned.

Medical News.

COLLEGE OF PHYSICIANS, IRELAND.—The diploma of Physician and Licentiate in Medicine was conferred on the 12th inst. upon the following gentlemen:—

*W. E. Dawson, L.S.A.L.; *C. J. Faulkner, L.R.C.S.; J. H. Foley, L.R.C.S.; G. B. Flanagan, L.R.C.S.; F. S. Gramshaw, L.R.C.S. Ed.; E. Lambkin, L.R.C.S.; B. Lane, L.R.C.S.; *A. J. Luther, L.R.C.S.; J. H. Maguire, L.R.C.S.; J. J. Norton, L.R.C.S.; D. M. O'Callaghan, L.R.C.S.; M. P. O'Donovan, L.R.C.S.; C. J. Penot, L.R.C.S.; *R. C. Thacker, L.R.C.S.

* Received in addition the Diploma in Midwifery and Diseases of Women.

SOCIETY OF APOTHECARIES.—The following gentlemen passed his examination in the Science and Practice of Medicine, and received certificates to practise, on the 11th inst.:—

Cook, Alexander, L.F.P.S. Glasg., Argyle-place, Edinburgh.
Stricker, Frederick W., M.B. Camb., M.R.C.S., St. Saviour's, Jersey.

Mr. William Henry Bowes, of Guy's Hospital, M.R.C.S., has been elected to the Surgical Scholarship of the Society of Apothecaries, of the annual value of £100. The examiners, Sir William Mac Cormac and Mr. Bryant, report that Mr. William Alexander Bowes McCabe, of University College, M.R.C.S., obtained a number of marks nearly equal to those of the successful candidate.

AFTER-CARE OF MENTAL CONVALESCENTS. — The anniversary meeting in connexion with this praiseworthy movement will, with the permission of Dr. Savage, medical superintendent, be held at Bethlem Hospital, on Thursday, July 2nd next.

AT the seventh annual meeting of the Home Hospitals Association for Paying Patients, held on the 10th inst., it was stated that through the greater part of last year there had generally been at least three applicants for each available bed.

AT the Aylesbury County Court on the 10th inst., Dr. Frederick Keene recovered £20 for professional services from a patient who wished that the principle of "no cure no pay" should apply to the medical profession as it did to his own trade—viz., that of an ironmonger.

ST. THOMAS'S HOSPITAL.—The annual presentation of prizes to the students of St. Thomas's Hospital took place on Monday, June 15th, in the Governors' Hall. The Lord Mayor, who presided, alluded to the ancient ties between the Corporation of the City of London and the hospital. He expressed himself as much gratified at the satisfactory reports given by the dean, Dr. Ord. The examinations showed that a remarkably large proportion of the students had attained a high degree of proficiency in their several subjects. Subsequently, a meeting of the old students of St. Thomas's Hospital was held in the library of the medical school, in order to present a testimonial to Mr. Charles Stewart. Dr. Ord, who spoke with much feeling, expressed for himself and for the school the deep affection in which Mr. Stewart was held. He alluded to Mr. Stewart's well-known capabilities as a teacher, his labours in comparative anatomy, and his success as curator of the museum. Dr. Ord went on to say that, much as his loss was regretted, a loss still acutely felt, all his old friends were pleased to see him in the important position of conservator of the museum of the Royal College of Surgeons. The fact that there were as many as 244 subscribers to the testimonial showed the widespread feeling of esteem entertained for Mr. Stewart. The list of prize-winners will, as usual, be published, along with those connected with other hospitals, in our Students' Number.

SANITARY INSTITUTE OF GREAT BRITAIN. — The autumn congress will be held at Leicester from September 22nd to 26th. A Health Exhibition, including sanitary apparatus and appliances in connexion with the Congress, will be held from September 22nd to October 10th.

PARLIAMENTARY ELECTIONS (MEDICAL RELIEF) BILL. In the House of Commons on the 15th inst., Mr. J. Collings obtained leave to bring in a Bill to provide that no person shall be disqualified from voting at Parliamentary elections by the receipt of medical relief for himself or his family. The Bill was read a first time.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—We understand that the new medical school in Caxton-street will be ready for opening by the commencement of the ensuing winter session (October 1st), and that the senior surgeon of the hospital, Mr. George Cowell, has been appointed to deliver the introductory lecture.

THE Lyons Society for the Protection of Children has offered prizes of gold medals for the years 1886 and 1887 for the best paper on the following subjects:—1. The different methods of vaccination; the age at which vaccination is best performed; and the prejudices to be combated in reference to the operation. 2. The study upon the influence of occupation upon pregnancy in women, the progress of pregnancy, and the vitality and health of children.

PRINTERS' PENSION CORPORATION.—At the fifty-eight anniversary festival of the Corporation which was recently held, it was stated that the needs of the Corporation were increasing rapidly, and that at the recent election of pensioners only twenty-one could be elected out of sixty-three deserving and necessitous candidates. The expenditure in pensions alone was £1900 per annum, a sum which was divided between nearly 150 pensioners, while the almshouses at Woodgreen afforded habitation for twenty-four inmates. During the evening subscriptions to the amount of £1018 were announced by the secretary.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH. -The usual monthly meeting of the members of this Association was held on the 11th inst., when Mr. Lawrence Booth read a paper on "Some Suggestions as to the Arrangement and Construction of Hospitals for Infectious Cases," illustrating his remarks by a series of drawings of an infectious hospital connected with Whittingham County Lunatic Asylum, now in course of erection, and of which he is the architect. A vote of thanks having been accorded to Mr. Booth for his paper, it was resolved to appoint a committee of five to confer with the London and other associations of the country with the view of improving the status of the medical officer.

Medical Appointments.

Information for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

BLACK, WM. G[illegible], M.R.C.S., has been appointed H[illegible] Surgeon to the Children's Hospital, Newcastle-on-Tyne, [illegible] term of office has expired.

C[illegible], H., M.R.C.S., has been appointed Clinical Assistant to the Surgical Out-patient Department, [illegible] Department, of the London Hospital.

H[illegible], CHARLES HENRY, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer of Health [illegible]

LAW[illegible], THOMAS C[illegible], M.R.C.S., L.S.A.Lond., has been appointed Medical Officer [illegible] District of the [illegible] Union, [illegible]

Leak, Hector, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Winsford District of the Northwich Union, vice A. P. Leak.

Limont, James, M.A., B.Sc., M.B., has been appointed Honorary Physician to the Newcastle-upon-Tyne Infirmary.

Lyle, Robert Charles, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Dunmow District and Workhouse, Dunmow Union, vice Clapham.

McMurray, John, M.D., M.Ch., M.A.O. Roy. Univ. Irel., has been appointed Assistant Medical Officer to the Parish Infirmary, Liverpool, vice J. G. Barns, L.R.C.P.Lond., M.R.C.S., resigned.

Pitt, George Newton, M.A., M.D., M.R.C.P., has been appointed Medical Registrar and Demonstrator of Practical Medicine to Guy's Hospital.

Roberts, Henry William, M.R.C.S., L.S.A.Lond., has been re-appointed Medical Officer of Health for the Deptford District, Greenwich.

Smith, D. Chadwick, M.D., B.Ch.Dub., has been appointed Medical Officer of Health for the Lowestoft Urban and Rural (Joint) Sanitary Authorities.

Stacpoole, Adam Richard, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Government Medical Officer and Vaccinator for the District of Corbar, New South Wales.

Stewart, G. Eland, M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Hospital for Diseases of the Throat, Golden-square.

Taylor, Moses, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Cannock District of the Cannock Union, vice Blackford.

Tibbits, Walter Hugh, M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the Districts of Manly and Pittwater, New South Wales.

Welsh, R. C., M.B., has been appointed House-Surgeon to the North Dispensary, Liverpool, vice John McMurray, M.D., elected to the Liverpool Parish Infirmary,

Births, Marriages, and Deaths.

BIRTHS.

Benton.—At Bennett-street, St. James's, the wife of Samuel Benton, M.R.C.S., of a son.

Bourke.—On the 10th inst., at Longridge-road, South Kensington, the wife of Surgeon Ulick J. Bourke, Army Medical Staff, of a son.

Cæsar.—On the 13th inst., at Minster in Sheppey, Kent, the wife of Julius Cæsar, L.R.C.P. &c., of a daughter (still-born).

Emerson.—On the 23rd ult., at Hampstead, the wife of P. H. Emerson, B.A., M.B.Cantab., of a daughter.

Hallows.—On the 13th inst., at Doncaster, the wife of H. Pinnington Hallows, M.B., C.M., L.R.C.S.E., of a son.

Lloyd.—On the 5th inst., at Ty'ncoed, Barmouth, the wife of H. J. Lloyd, L.R.C.P. &c., of a son.

Macdowell.—On the 15th inst., at Otter Holt, Carlow, Ireland, the wife of Charles Macdowell, M.D., F.R.C.S., of a son.

Nicholls.—On the 23rd ult., at Dominica, West Indies, the wife of H. A. Alford Nicholls, M.D., F.L.S., of a son.

Smith.—On the 14th inst., at Russell-road, Kensington, the wife of W. Towers Smith, M.R.C.S., of a daughter.

MARRIAGES.

Gibb—Adamson.—On the 10th inst., at Ava Lodge, Magdalen-green, Dundee, William Gibb, L.R.C.P.Ed. &c., to Annie, second daughter of John Adamson, Esq.

Harper—Sutcliffe.—On the 3rd inst., at the Parish Church, Burnley, Robert Russell Harper, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., of Littlebury House, Holbeach, only son of R. Harper, Esq., J.P., of Holbeach House, Lincolnshire, to Marian, only daughter of Edward Sutcliffe, Esq., of Holme View, Burnley.

Macdonnell—Barlow.—On the 11th inst., at the Church of St. John the Evangelist, Montreal, Richard Lea Macdonnell, M.D., son of the late Dr. Robert Lea MacDonnell, of Montreal, to Constance Anne, only daughter of the late Francis W. Barlow, Esq., of Bickley, Kent.

DEATHS.

Baillie.—On the 11th inst., at his residence, 87, Prince of Wales-road, Haverstock-hill, N.W., Dr. Benjamin Tillyer Blunt Baillie, aged 57.

Bernard.—On the 10th inst., at Durrance House, Hemel Hempstead, suddenly, George Peterson Bernard, F.R.C.S.

Carver.—On the 16th inst., at Fairlawn, Fulham, Mary, the dearly loved wife of Eustace John Carver, aged 38.

Gray.—On the 6th inst., at Lansdowne House, Essex-road, London, Thomas Scott Gray, M.D., M.R.C.S., L.S.A.Lond., aged 59.

Holton.—On the 12th inst., at Randolph-gardens, Kilburn, Francis Holton, M.B., Surgeon-General (retired), Army Medical Service, aged 59.

Lobb.—On the 13th inst., at The Hermitage, Wyer Hall, Edmonton, William Lobb, M.D., in his 82nd year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 22.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10.30 A.M., and each day at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 P.M., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 P.M., and on Tuesdays at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

Royal College of Surgeons of England.—4 P.M. Professor Charles Stewart: Inflammation.

Tuesday, June 23.

Guy's Hospital.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

Cancer Hospital, Brompton.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 2.30 P.M.

Central London Ophthalmic Hospital.—Operations, 2 P.M., and on Friday at the same hour.

Anthropological Institute of Great Britain and Ireland.—8 P.M. Lady Brassey: Exhibition of Objects of Ethnological Interest from Polynesia.—Miss North: Exhibition of Ethnological Objects from New Ireland.—Mr. Carl Lumholtz: Exhibition of Australian Implements.—Mr. H. P. Guppy: On the Physical Characteristics of the Natives of the Solomon Islands.—Mr. Abraham Hale: On the Sakais.—Mons. Jean L'Heureux: Notes on the Astronomical Customs and Religious Ideas of the Chokitapia or Blackfeet Indians.—Mr. Hyde Clarke: Observations on the Mexican Zodiac and Astrology.—Mr. James Dallas: On the Primary Divisions and Geographical Distribution of Mankind.

Wednesday, June 24.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

St. Mary's Hospital.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

St. Thomas's Hospital.—Operations, 1.30 P.M., and on Saturday at the same hour.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Central Hospital.—Operations, 2 P.M.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 P.M.

University College Hospital.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

Royal Free Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 3 to 4 P.M.

Royal College of Surgeons of England.—4 P.M. Professor Charles Stewart: Inflammation.

British Gynæcological Society.—8.30 P.M. Specimens will be shown. Adjourned Discussion on Dr. More Madden's paper on Fibro-myomata.

Thursday, June 25.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Surgical Consultations, 1.30 P.M.

Charing-cross Hospital.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2.30 P.M.

Friday, June 26.

St. George's Hospital.—Ophthalmic Operations, 1.30 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

King's College Hospital.—Operations, 2 P.M.

Royal College of Surgeons of England.—4 P.M. *Professor Charles* Stewart: Inflammation.

Saturday, June 27.

King's College Hospital.—Operations, 1 P.M.

Royal Free Hospital.—Operations, 2 P.M.

Middlesex Hospital.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

HONE STONES.

IT may be useful to some of our readers to have their attention directed to good and serviceable hones, specimens of which have been submitted to our inspection from the quarries of Mr. Montgomerie, of Dalmore, Stair, Ayrshire. The "Tam o' Shanter" hones are very neat in appearance, and for whetting delicate cutting instruments are decidedly useful and efficient. They may be obtained cased or uncased, and in different sizes.

Mr. Stretch Dowse.—We are not at present in possession of information beyond that given in our last issue.

Equality will be liable to duty for the whole of the vehicles.

THE TITLE OF "DOCTOR."

To the Editor of THE LANCET.

SIR,—To give the two London Colleges the power of granting a degree in Medicine, or the title "Doctor," would not only be a flagrant injustice to existing graduates, but would also be productive of much injury to all the universities, from Oxford downwards; and I cannot think that any one of the delegates from the Royal College of Physicians will be found so wanting in duty to his *alma mater* as to sanction any such gross violation of vested interests. It would practically be raising the status of the Colleges from licensing corporations to a university of one faculty only. Why should they be so favoured in being allowed to forego the responsibilities of faculties of arts, law, and science, without which there can be no *raison d'être* for any university? Let us suppose for a moment that every M.R.C.S. and L.R.C.P. will wake up some fine morning and have the right to dub himself "Doctor." Where will be the privilege when all distinction is abolished? Whose will be the benefit, if we except the door-plate engravers? In a word, the one reason for the present outcry is that the institution in Burlington-gardens has failed egregiously in its duty to the profession and the public. The true remedy for the grievances of non-graduates is the reform of the University of London; or its abolition, coupled with the establishment of a new body under a charter so framed that the lessons of the past fifty years should not have been learnt in vain.

I am, Sir, your obedient servant,

June 8th, 1885. L.R.C.P.Lond.

Mr. J. B. J. O'Meara must not be too much disturbed by the judgment of the lay press in such a case, especially after the expression of opinion of the Board. The patient had *only* to have requested a visit for one to be paid, and in the nature of the circumstances casual visits were not to be expected, though, of course, they would have been greatly appreciated.

Mr. George D[illegible] (Berlin).—The review has not escaped our notice.

"HEALTH ASSURANCE ASSOCIATIONS."

To the Editor of THE LANCET.

SIR,—Permit me to correct an error which occurs in my letter on this subject in your last issue. In the sentence, "The patient is brought into an intimate and friendly relation with his client," for "patient" read doctor.

I would just like to add explicitly that the way to nip these new associations in the bud is simply to adopt the system of health assurance in our practices; and lest there should be any of my professional brethren who do not know what health assurance is, or how it is practised, I may say that I shall be happy to send a copy of my pamphlet on the subject to any medical man who desires it, on receipt of a stamp for postage. Specimens of the printed forms employed in health assurance will be ready for distribution in the same way in about a fortnight.

I am, Sir, yours very truly,

W. FLEMING PHILLIPS.

St. Mary Bourne, Andover, Hants, June 13th, 1885.

TREATMENT OF DIPHTHERIA.

IN reply to the request of "L.S.A." in our last issue for information on this subject, we have received answers from several correspondents.

Mr. Walther states that cyanide of mercury in small doses has been given with marked success. He has employed it in doses varying from gr. $\frac{1}{48}$ to gr. $\frac{1}{16}$, according to age, every six hours for the first few days, followed by the perchloride of iron. Sulphurous acid was applied locally at the same time.

Mr. Dixon recommends the administration of belladonna, and remarks that as an antiseptic remedy of great value benzoate of sodium doubtless ranks amongst the first. A remedy he has employed with success is a mixture of chlorate of potash, perchloride of iron, and glycerine.

Mr. T. H. Sutell records the success which attended the administration of brandy very freely, emetics, and perchloride of iron (in milk, to cover the taste), and no interference with the throat.

Dr. Illingworth suggests the following prescription for children of from three to eight years:—Sodæ salicylatis, ʒss—ʒj; sp. am. aromat., ʒj—ʒij; syr., ℥ss; aq. ad ℥ij. M. et solve. Sig.: Capiat cochlearia parva secundis horis. He also expresses his intention of using in his next case of diphtheria a mixture of tannic and carbolic acids in glycerine, in the proportions of one part carbolic to twenty of glycerine and the usual one of tannic acid.

M.R.C.S.E. &c. suggests the use of the concentrated solution of pepsin as employed, and highly praised, by Dr. Edwin Rosenthal:—Jensen's pepsin, ʒj; acid. hydrochlor., gr. xx.; aquæ q. s. ft. ℥j. Apply to throat every hour. Support the powers of life by nutritious and stimulating liquid diet.

Mr. F. Porter Smith.—The case seems to be one of which the College ought undoubtedly to take notice.

Dr. H. M. Lawren (Cuthbert, Georgia).—We cannot promise insertion of the paper until the MS. is in hand.

FOR THE GOOD OF HUMANITY.

To the Editor of THE LANCET.

SIR,—Probably there is no class of men whose opinion is more generally sought and respected than that of the "family doctor"; and it appears to me that the subject whereupon that influence might have largest scope, and be the means of benefiting humanity to an almost inconceivable extent, is one which, except by a very *few*, is completely avoided. In a large and varied experience, it has appalled me to find how lamentably ignorant nine out of ten women are concerning the influence of the mother upon the fœtus. This is a subject upon which physiological research has resulted in an almost, if not quite, unanimous verdict, and it is barely conceivable that any physician who has conscientiously weighed the question can fail to see it his plain duty to use his influence and knowledge, justified by his profession, and probably by experience also, in one of the noblest causes for which men can toil—namely, the good of the race. In these days, when immorality is so rife and its consequences so inimical both to the individual and the State, it befits us to search deeply for the cause, and to ask ourselves what can we do, and, among medical men at any rate, the answer is not far to seek. It would be an easy matter to point out to mothers the absolute necessity of common-sense clothing and healthy exercise, for the perfect development of the child; the cultivation of lofty aims, and all we hold to be of the highest good, if they would wish to see them in the possession of their descendants; and just as they would avoid any depressing or frightful influence or sight, or any sudden surprise, so every other undesirable emotion is also to be guarded against, and the whole being brought into as perfect subjection to the will as possible. And there remains another even more important direction in which to urge the necessity of self-control. We all know too well the frightful results, among all classes, of juvenile vice, the hideous increase of juvenile prostitution. Where is the remedy? Education? It is too late! We must begin at generation. To go to the root of the matter. Who that has studied the question doubts for a moment that it is the violation of those laws which hold good throughout the whole animal creation, and which in the case of women only are broken, that it is the unrestraint of the sexual function during pregnancy that transmits to the fœtus abnormally developed tendencies in the organs of generation by the undue exercise of those organs in the mother when nature demands rest, thereby probably influencing the progeny to a greater extent than by the similar indulgence of any other mental or physical quality in proportion to the greater susceptibility of these organs to become exaggerated and abnormal in their action? It is even more important that these grave facts should be brought under the consideration of husbands; for in the case of the majority of women nature is a law to herself, and prompts abstinence. Doubtless the sin is one of ignorance, not intention; but the law remains, and the penalty also—"The sins of the fathers are visited on the children to the third and fourth generation." It is the everlasting strife between good and evil: whether man will transmit beneficial or harmful tendencies; whether his children shall be slaves to or masters of their passions; whether he will make it more or less easy for them to live pure and healthy lives, thus adding his quota towards the elevation of the race. No one has the same opportunity of spreading these great truths as those in the medical profession; therefore I take the liberty of begging that you will lay these suggestions before them by means of your valuable journal.

I am, Sir, yours faithfully,

Eastbourne, June 11th, 1885. J. T.

THE PROVIDENT SYSTEM AND THE OUT-PATIENT DEPARTMENT.

X. Y. Z. would like to know if in any case the provident dispensary system has been adopted by the out-patient department of a general hospital, and with what result.

H. J.—1. The question has been repeatedly answered in our columns.—2. Application might be made to the Registrar.

Alp.—Next week, if possible.

"TREATMENT OF ACUTE PERITONITIS BY ABDOMINAL SECTION."

To the Editor of THE LANCET.

SIR,—In a letter under the above heading in your last issue Mr. Lawson Tait gives the credit of first opening the abdomen "under acute symptoms" to Dr. Wiltshire. Dr. Wiltshire's case occurred in May, 1868. In December, 1864, my father, Dr. Keith, removed an ovarian tumour from a patient suffering from symptoms of the utmost gravity, due to peritonitis and gangrene of the tumour. That he did so deliberately is shown by the following extract from the report of the case, which appeared in THE LANCET of July 8th, 1865, nearly three years before Dr. Wiltshire's operation: "Though the practice adopted seemed at the time to be rash, and scarcely justifiable, yet it saved the life of the woman." Again, referring to this case in the *Edinburgh Medical Journal* of February, 1875, Dr. Keith says: "The pain was not relieved, abdominal distension from flatus became excessive, and typhoid symptoms rapidly set in. Fearing a repetition of the slow death process—which those who saw will not easily forget—ovariotomy was this time performed during the semi-delirium of septic fever. This was probably the first time that surgery broke in on an inflamed peritoneum, &c."

I am, Sir, your obedient servant,

Edinburgh, June 16th, 1885. SKENE KEITH, F.R.C.S.Ed.

An Army Doctor.—Why do not the medical officers take the matter into their own hands? If inquiry be made into what has been done on former occasions in reference to the grievance, the remedy will become readily apparent.

F. C.—The method of announcement is certainly objectionable.

CHRONIC ECZEMA OF THE AURICLE.

To the Editor of THE LANCET.

SIR,—I have lately had several cases of inveterate eczema of the auricle. In all the disease had lasted for years, and had resisted all the ordinary modes of treatment. I do not think any of the patients were gouty or scrofulous. In each case a speedy and perfect cure was accomplished by blistering the affected surface. Two or three applications of a weak solution of croton oil in absolute alcohol will suffice. It appears to me that in these cases the disease has no constitutional origin, but is due to a local neurasthenia, and hence the failure of the usual applications and internal remedies.

I am, Sir, your obedient servant,

Wick, June 11th, 1885. A. G. AULD, M.B.

PORTER, GARDENER, *AND* DISPENSER.

To the Editor of THE LANCET.

SIR,—I enclose an advertisement which appeared in last week's *Pharmaceutical Journal*, which will show to what low degree the art of dispensing has fallen.

"A Porter and Gardener (one who can Dispense Medicines preferred), at the Grantham Cottage Hospital.—Apply, stating age, whether married, wages required, and other particulars, to G. W. G. Beaumont, Hon. Sec., Hospital, Grantham."

I am, Sir, yours obediently,

Marylebone-road, N.W., June 15th, 1885. JOHN WOODLAND.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Elder, Nottingham; Mr. Lawson Tait, Birmingham; Professor Buchanan, Glasgow; Dr. Cruise, Dublin; Mr. Dalby, London; Dr. Cobbold, London; Mr. Gardner, London; Mr. H. R. Davies, London; Mr. W. A. Ellis, London; Mr. Skene Keith, Edinburgh; Dr. Althaus, London; Dr. H. B. Baker, Lansing, Michigan; Mr. H. Hawkins; Mr. F. Fox, Strathpeffar; Dr. H. M. Lawson, Cuthbert, Ga.; Mr. J. Marshall, Glasgow; Mr. Auld, Wick; Mr. Bruce Joy, London; Mr. G. Duncan, Berlin; Dr. R. T. Cooper, London; Mr. Hopkins, London; Mr. T. H. Sawtell, London; Mr. J. Walther, Eastbourne; Dr. Roman von Baracz, Lemberg; Dr. S. Dowse, London; Mr. D'Orsey; Mr. Coates, Sirhowy; Mr. Williams, Much Hadham; Mr. Wood, Yokohama; Mr. George, Liverpool; Mr. Stilliard, Birmingham; Dr. Gamgee, Birmingham; Dr. Emerson, Southwold; Messrs. ABSTRACT OF TWO

Clinical Lectures

ON

INTRA-CRANIAL SYPHILIS.

Delivered in the Western Infirmary of Glasgow.

By DR. McCALL ANDERSON,

PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW.

LECTURE I.

Gentlemen,—We have at present in the wards three illustrations of intra-cranial disease which, while they present certain features in common, differ considerably from one another in respect to their symptomatology; and yet, as we shall see, they are but branches of one and the same parent stem.

But first of all let me refer to a case of a similar nature which some of the senior students had the opportunity of seeing, the patient having been admitted into Ward 9 on March 30th, 1882. This man—who was twenty-nine years of age, and a grinder by occupation—was then suffering from left-sided hemiplegia. He informed us that for six months he had been troubled with severe and steadily increasing headache, which was limited to the left side. Four days before he came to us he was, in addition, quite suddenly seized with paralysis of the left arm and leg, so that he was unable to walk, and the day following it was observed that he could not converse, but could only answer "Eh!" to every question that was put to him. The day before admission, however, this symptom had in great measure disappeared, although when he came into the infirmary he had a dazed and stupid look, and answered questions in few words or sometimes not at all, while the information which he vouchsafed was found afterwards to be quite erroneous. For a day or two also before admission the paralysis, which was quite complete at first, except as regards the side of the face which was only partially paralysed, became much less pronounced, so that he could move the arm a little and the leg with considerable freedom. On the 8th of April, nine days after he came under observation, he became insensible, the loss of consciousness lasting for about a quarter of an hour, during which time there were convulsive movements of the arm and leg. On recovering consciousness it was found that the paralysis was greatly aggravated, he being unable to move either the arm or leg. The sensation, too, on the same side of the body was rather defective as regards touch, pain, and temperature. Thus, when slightly pricked with a needle, he thought he was touched with the hand, and when hot and cold sponges were applied he could discriminate cold, but not heat.

The symptoms present in this case showed that the lesion was situated on the right side of the brain, so as to involve the motor, and to a less extent the sensory tract. As regards the nature of the lesion, embolism as a cause of the hemiplegia was very unlikely, because it is then generally right-sided; because of the absence of any evidence of deposits on the mitral or aortic valves such as most commonly yield emboli; and because there were no signs of embolism of other organs. The age of the patient, and the absence of symptoms of kidney disease or of degeneration of vessels, rendered a cerebral hæmorrhage improbable. On the other hand, the intense and long-continued hemicrania led to the suspicion that we had to deal with a cerebral tumour, and that it was of a syphilitic nature we concluded from the following facts. The hemicrania was markedly nocturnal in character, as we so often find in syphilitic cases; the skin had a dirty, earthy, pallid appearance; the inguinal and arm glands were distinctly enlarged; and a large white scar about the size of a sixpence, with dark edges, was discovered about the root of the penis, which we were told on inquiry was the result of a chancre which he had five years before. This view was further confirmed by the result of treatment, which consisted in the rubbing of a drachm of strong mercurial ointment into a fresh part of the skin every day. It was commenced on [illegible], omitted by mistake from the 10th to the 20th, and finally stopped on June 2nd. On June 23rd, when he left the hospital, he was a very different man. The intelligence, which was at first so defective, was perfect in every respect, the nocturnal hemicrania had long since disappeared, the paralysis of the arm was very slight, as he could move it freely in all directions, and the dynamometer, on which at first the left hand made no impression, registered thirty-five kilogrammes. The paralysis of the leg was likewise slight, although rather more pronounced than that of the arm, and he walked a little lame and rather stiffly. This last symptom, taken along with the existence of some tremor when the limb was manipulated, and exaggeration of the patellar-tendon reflex (the ankle clonus was not present), rendered it probable that secondary sclerosis of the lateral column of the cord had to a certain extent occurred. As this lesion, although secondary to the lesion in the brain, was of a non-syphilitic character, it could not be expected to be benefited by anti-syphilitic treatment.

We now pass on to the consideration of the cases at present in the wards. The first to be admitted (Feb. 10th, 1885) was a blacksmith, thirty-eight years of age. He complained chiefly of severe pain in the forehead and upper part of the head, which had been present for about four months. The family history was good. Twelve years ago he suffered from an attack of gonorrhœa, which lasted about three or four months, and did not appear to have left any bad results. About eight years ago he had what he calls rheumatism, describing it as constant pains in the bones and joints, becoming very bad on movement and markedly worst at night. Three years ago he had a painful affection of the throat lasting for about a year. With the above exceptions he had always been a healthy man previous to the onset of the present illness. About four months ago he was suddenly seized, while sitting at the fire, with a violent pain in the forehead above the left eye. It lasted several hours, and he was then free of it for about a fortnight. After that he had repeated attacks, and noticed that the intervals between them gradually became shorter, and since the beginning of the year they had been almost constantly present, although with occasional great exacerbations. It was worse at night. The pain above described was often very intense, so much so as altogether to prevent sleep, and frequently to produce delirium. About the beginning of January his eyesight became somewhat impaired, so that he was unable to read as well as he used to do. On looking at anything steadily for a time, his vision became dim, as if a "scum" was before his eyes, and sometimes there was a feeling of pressure in them, especially on attempting to read. He professed never to have had any eruption on the skin or falling out of the hair. During the three months previous to admission he had lost flesh very much, having become, as he thought, about three stones lighter than formerly. A few scars were observed on the legs, which he said were due to the application of croton oil. The scar on the right leg, a little above the outer malleolus, was distinctly coppery in tint. There was a rounded and depressed cicatrix on the glans penis a little above and to the left of the frænum. This he attributed to a burn from a piece of live coal. The foreskin was adherent to the glans at the sulcus. There were no scars at the angles of the mouth. There was no paralysis of the muscles of the face or eyelids, save a slight drooping of the left upper lid. The eyeballs were slightly prominent, especially the right, but this condition, he said, had been present since childhood. The tongue, on being protruded, appeared to be slightly drawn to the left side. On tapping all over the head two spots were found about two inches and a half above the outer angle of each eye, which were distinctly tender. He could hear the ticking of a watch better when placed opposite the ear than on the temple. The greatest distance he could hear the watch with the left ear was eighteen inches, with the right twenty-four. The smallest type he could read on admission was a double small pica, whilst before the illness he could read the ordinary type of a newspaper, which is only half the size of the above (see Dr. [illegible]).

[illegible]

No. [illegible]

C c

Smell and taste seemed to be normal, and the dynamometer registered 105 kilogrammes with each hand.

A consideration of the history and symptoms present in this case led to the conclusion that we had to deal with intra-cranial syphilis. Before his admission into the infirmary he had been under the care of half a dozen medical men in succession, and appears to have been treated for the most part by means of quinine and other anti-neuralgic remedies. His last medical adviser, however, evidently suspected the syphilitic nature of his complaint, and gave him iodide of potassium. He took it at first in doses of ten grains three times a day, but for a week before his admission the dose was increased to thirty grains. This had not the slightest effect upon the pain or other symptoms. Accordingly, on the 12th of February, he was ordered to rub into the skin daily one drachm of Shoemaker's mercurious oleate ointment, while thirty minims of paraldehyde were prescribed at night to procure sleep. In a few days the pain had completely disappeared, and up to the present date (April 1st) he has remained perfectly well. The mercurial treatment is, however, being continued as a precautionary measure.[2]

WHY DOES SALICYLIC ACID CURE RHEUMATISM?

By P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

(Concluded from p. 1121.)

IF, then, as I assert, uric acid or its antecedent is the *materies morbi* which develops rheumatic fever, and if, as I have previously advocated, it is according to the accepted opinion the cause of gout, why should it in some individuals produce this disorder and in others rheumatism?

Let us in the first place consider what, under the normal state of things, is the effect of cold and heat applied to the surface of the body. The effect, as you know, is very different as regards cold-blooded and warm-blooded animals. External cold diminishes and heat increases the metabolic activity of the cold-blooded animal, acting like a mixture of dead substances in a chemical retort. But in a warm-blooded animal, within certain limits, cold increases and heat diminishes the bodily metabolism, as shown by the increased or diminished consumption of oxygen and production of carbonic acid as the temperature falls or rises. There is obviously a mechanism of some kind counteracting and indeed overcoming those more direct effects which alone obtain in cold-blooded animals. But under the influence of urari, which paralyses the end-organs of the muscular nerves, a warm-blooded animal behaves as regards its bodily metabolism under the influence of external cold and heat like a cold-blooded animal. "We can best explain these results by supposing that under normal conditions the muscles which, as we have seen, contribute so largely to the total heat of the body are placed, by means of these motor nerves and the central nervous system, in some special connexion with the skin, so that a lowering of the temperature of the skin leads to an increase, while a heightening of the temperature leads to a decrease, of the muscular metabolism. Further, though the matter has not been fully worked out, the centre of this thermo-taxic reflex mechanism appears to be placed above the medulla oblongata, possibly in the region of the pons Varolii. When urari is given the reflex chain is broken at its muscular end, when the spinal cord is divided the break is nearer the centre."[1]

How does this bear upon rheumatism? An individual is exposed to a cold draught or gets wet; the surface is chilled; the cutaneous vascular areas are constricted; by reflex action through the vaso-motor system the splanchnic vascular areas and the vessels of the muscular areas are dilated; the vaso-motor nerves distributed to these parts are paralysed, so to speak; with this paralysis of the vaso-motor nerves of the parts there is not only a dilatation of the vessels in the part, but there is also a weakening of the power by which the albuminous molecules are held together, and from both causes heat is developed. The normal change of the cyan-alcohols into cyanamides, and amido-acids with the ultimate oxidation of the latter, is modified. The molecules $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ and $C_2H_4\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ become detached from the benzene nucleus, and more or less from each other, and by hydration (by which heat is developed) form substances—glycollic acid and lactic acid—which are more easily oxidised than the amido-bodies. The oxygen, though conveyed in larger quantities than normal by the increased blood-supply to the tissue, is completely used up in oxidising the glycollic and lactic acids which have been formed; the excess of lactic acid and the glycocine (which has also been formed) are unoxidised and pass into the circulation. Now, in a normal or healthy state of things, the irritating or stimulating cause acting on the skin being removed, reaction would be set up there, the cutaneous vascular area would dilate, and consequently the vessels of the muscular area would contract, and this latter contraction would be increased by the stimulating effect of the glycocine or resulting uric acid, which, being a morbid product, would stimulate, as in gout, that portion of the nervous system which controls the nutrition of the joints just in the same way as carbonic acid in the blood stimulates the respiratory centre. In this way less blood would go to the muscular area, and the albuminous molecules would again be held more firmly together and undergo the normal changes, the uric acid being meanwhile excreted by the kidneys and the lactic acid by the skin. I have here drawn you a picture of an ordinary feverish cold—the primary chill, the ensuing febrile condition, the elimination of lithates with the subsidence of the attack.

But suppose the individual who is exposed to damp or cold has been previously reduced in strength, is tired out or exhausted—that is to say, his vaso-motor system is in a weak state, the weakness either developed from the above causes, or it may be inherited. Then following the chill there would be the same effects produced as I have above described, but the vaso-motor nerves regulating the vessels of the muscular area would be more completely paralysed, and when reaction set in on the surface of the skin there would be less power in the muscular nerves to recover from that paralysed condition; and more than this, the central portion being exhausted, the stimulus of glycocine or uric acid produces not stimulation, but exhaustion.

Let me illustrate what I mean by reference to the sciatic nerve.

"Division of the sciatic nerve of a mammal causes dilatation of the small arteries of the foot and leg. Where the condition of the circulation can be readily examined, as, for instance, in the hairless balls of the toes, especially when these are not pigmented, the vessels are seen to be dilated and injected, and a thermometer placed between the toes shows a rise of temperature amounting, it may be, to several degrees.[2] But the dilatation so caused after a few days disappears; the foot on the side on which the nerve was divided becomes not only as cool and pale, but frequently cooler and paler than the foot on the sound side. If the peripheral portion of the divided nerve be stimulated with an interrupted current immediately or very shortly after division, the dilatation due to the division gives place to constriction; the sciatic nerve acts then quite like the cervical sympathetic, except perhaps that this artificial constriction cannot be maintained for so long a time, and is very apt to be followed by increased dilatation. If, however, the stimulation be deferred for some days, until the dilatation has given place to a returning constriction, the effect is not constriction, but dilatation; the nerve then acts, so far as its vaso-motor fibres are concerned, like a muscular nerve, and not like the cervical sympathetic.[3] So also with regard to the mylohyoid muscle. Section of the nerve produces dilatation, but the dilatation is transient. The vessels speedily return to their former calibre, and then it is found that stimulation, of whatever strength, of the peripheral portion of the divided nerve brings about not constriction, but dilatation. If then the vaso-motor fibres of the muscular nerves have been weakened, the result would be that the normal stimulating effect of uric acid on the motor nerves generally

---

disc; but no distinct evidence of there having been choked disc or engorged optic nerve, the disturbance not being more than is sometimes found in a high degree of hypermetropia. The defect of vision which he complains of is to be referred to deficient power of accommodation rather than to actual loss of accommodation. This deficient power of accommodation is sometimes seen to follow a shock to the nervous system."

[2] This patient was seen on April 27th, and was found to be quite as well as at the beginning of the month.

[1] Foster's Physiology, 4th edition, p. 467.

[3] Ibid., p. 2[illegible].

would be transformed into a depressing or paralysing effect on the enfeebled nerves, the vessels of the muscular area would be still further dilated, the albuminous molecules would be loosened, hydration and oxidation would go on causing fresh development of heat, there would be the continuous formation of uric acid and lactic acid, the uric acid accumulating in the system, and producing its deleterious effect and modifying the function of the nervous system; the lactic acid dilating the smaller arteries[4] and stimulating the sweat centres, passing off in part by the skin. With increased stimulation of the paralysed centre of the muscular nerves complete dilatation of the vessels in the muscular area will take place, the albuminous molecules now fall completely asunder, the $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ and $C_2H_4\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ being entirely hydrated into glycollic acid and lactic acid with the rapid production of heat, and the heat is further developed by the ready oxidation of these products. In this way the so-called hyperpyrexia of rheumatic fever is produced.

But whilst uric acid affects in this way the vaso-motor fibres of muscular nerves, it also affects the nutrition of the joints. We see that in gout; it stimulates and alters the nutrition of the part, and as the blood contains an abnormal substance, this is deposited about the joint in the form of urate of soda. Uric acid increases, too, the oxidation going on in the part, for there is increased heat. These changes are the result of the irritative effect of the uric acid upon the neighbourhood of the medulla oblongata and motor tract. Why I fix upon this as the part specially affected, I will explain presently. But at the age when gout appears, the sympathetic system and the vaso-motor fibres are less susceptible than in former years to irritative causes. Cold applied to the surface of the body in a person of advanced years does not result in increased heat or reaction, but produces internal congestion, pneumonia, hæmaturia, diarrhœa, &c. In gout the uric acid is the result of modified innervation of the liver, causing a paralysis of the hepatic vessels and lessening of the normal metabolic changes, and so there is non-transformation of the glycocine and the consequent formation of uric acid. In rheumatism the glycocine results from changes in the vascular area and in the metabolism of the muscles, and along with its formation there is also the formation of lactic acid by hydration, both from the cyan-alcohol $CH_2 . CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ and the cyan-alcohol $CH_3 . CH\left\{\begin{matrix}OH\\CN\end{matrix}\right.$; the nutrition of the joint is modified, as in gout, by the stimulating effect of the uric acid on the centre of the muscular nerves, but the nutrition is further modified by the presence of the lactic acid in the blood, producing dilatation of the arterioles, more particularly round the affected parts. For both diseases therefore the treatment resolves itself into neutralising or getting rid of the glycocine, and so preventing the formation of uric acid and putting a stop to the irritating effect of it on the centre of the muscular nerves. This is effected in large measure by salicylic acid. The glycocine and some portion of the lactic acid in the muscular tissues is derived, as I have shown, from methene cyan-alcohol, $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$. The salicylic acid combines with this as it parts from the albuminous compound forming

$$\begin{matrix}CH_2\\C_6H_4\end{matrix}\left\{\begin{matrix}DH\\CN . OH\\COOH\end{matrix}\right.$$

which produces no irritating effect on the nervous centre, and as it passes out of the body is transformed, as is previously shown, into $CH_2(NH . C_7H_6O_2)COOH$, or salicyluric acid.

But along with this remedy the judicious use of cholagogue purgatives will be of great benefit, by eliminating the bile from the intestines, and so removing a quantity of glycocine from the system. And, lastly, the proper diet to employ is one as free from glycocine as possible—that is, one consisting chiefly or entirely of milk and farinaceous food. From what I have said it is also easy to understand how a number of blisters applied near the affected joints may often cure the disease—viz., by reflex action on the vessels of the muscular area, causing them to contract, and so diminishing the metabolism and lessening the formation of glycocine.

A word or two, lastly, with regard of the pathology of that form of diabetes which originates in the muscular tissue. In my previous paper I have indicated the way in which I think it probable that glucose may in the living body be derived from albuminous material—namely, by the separation of the molecules of $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ from the benzene nucleus, their hydration into glycollic acid, $CH_2\left\{\begin{matrix}OH\\COOH\end{matrix}\right.$, and their oxidation into CO_2 and methyl aldehyde, $H . CHO$, and water; the oxidation being arrested here, and condensation of six molecules of the aldehyde taking place, forming $C_6H_{12}O_6$, or glucose. Here we have, then, a condition resembling somewhat that associated with hyperpyrexia, except that the oxidation is in some measure inhibited. The vaso-motor fibres of the muscular nerve are paralysed, the molecules $CH_2\left\{\begin{matrix}OH\\CN\end{matrix}\right.$ are detached and hydrated, but only *partially* oxidised; the tissue is, so to speak, partially urarised, the aldehyde is not oxidised, but condenses into glucose. In urari poisoning sugar appears in the urine, though "the exact way in which this form of diabetes is brought about has not yet been clearly made out."[5]

Now, you will find that in some forms of diabetes salicylic acid is of the greatest importance, whereas in others no good results from its use. The urine in the former cases contains often, in addition to glucose, an excess of uric acid, and the patients suffer from neuralgic pains in the joints and limbs. Their diabetes is said to be "gouty"; but it seems to me that the presence of the glucose in the urine is due to the uric acid and *some* of the muscular tissue, in the manner above indicated.

Gentlemen, I have already trespassed upon your patience too long; I will, therefore, only very briefly indicate on what grounds I localise that portion of the nervous system which controls the nutrition of the joints, and the function of which is affected by uric acid, about the medulla oblongata and the motor tract.

1. Rheumatism not infrequently after a short interval follows tonsillitis. Now, we may assume either that the condition of the central nervous system in the individuals so affected is such that the slight injurious influences acting upon that portion of the central nervous system will produce an attack of quinsy, whereas more severe injurious influences will cause rheumatic fever; or we may assume that in quinsy the irritation of the nerves distributed to the tonsils not only affects the central nervous system at the origin of the roots of the nerves supplying the irritated part, but through the sympathetic nervous ganglia the irritation radiates to other parts of the nervous system which are in connexion with that ganglion. Either hypothesis will answer my purpose. The tonsillar nerves are derived from the fifth nerve—the middle descending branch from Meckel's ganglion—and from the glosso-pharyngeal portion of the eighth nerve. This branch of the fifth, to which I have referred, is derived from the larger root of the nerve which may be traced back to the lateral tract of the medulla oblongata immediately behind the olivary body, and is connected with the grey nucleus at the back part of the medulla between the fasciculi teretes and the restiform columns. The deep origin of the glosso-pharyngeal may be traced through the fasciculi of the lateral tract to a nucleus of grey matter at the lower part of the floor of the fourth ventricle, external to the fasciculi teretes. Both these nerves receive filaments from the superior cervical ganglion of the sympathetic.

2. In locomotor ataxy, associated with sclerosis of the posterior and lateral columns of the spinal cord, the joint affection known under the name of Charcot's ataxic arthritis sometimes presents itself. At the present moment we have in the hospital here a case of this kind, showing very conclusively the connexion between swelling of the knee-joint and irritation at the root of the fifth nerve, and in particular of the root of the anterior dental branch.

P. R——, aged fifty-nine, was admitted into Addenbrooke's Hospital Jan. 19th, 1885. At seventeen years of age he had pleurisy; during convalescence the right knee began to swell. Four years later the thigh was amputated owing to disease of the knee-joint. For twelve years after that he had good health, and then was suddenly attacked one night with sharp pain in the stump. In the morning he had neuralgia affecting the middle division of the fifth nerve. This case on regularly for eighteen months at 11 A.M., and since then has been very nearly continuous, but with exacerbations. He had ague when thirty-nine years old. At intervals there has been pain in the stump. He has had all his teeth removed from the upper jaw excepting one carious stump, on account of the pain, but without any relief. For the last three years he has noticed that at times he could not pass water, and at others it would run away from him. He has had aching pains in the left tibia for four years, but never had any lightning pains. In August, 1884, he suffered from violent abdominal pain lasting three months, and attended with sickness. He complains now of great pain in the upper gum, and compares it to that produced by a red-hot iron passed along the upper gum from the centre to the back, the attacks coming on at intervals of a few minutes, and lasting about ten seconds. On March 2nd he complained of numbness in the left leg, pain at the lower end of the femur and outer side of the thigh. There is no patellar reflex, no ankle clonus. The leg and thigh subsequently became œdematous and brawny, the knee-joint became distended and contained fluid, the ligaments very lax, allowing very free lateral movement; no creaking; no bony outgrowth was discovered. As this swelling of the leg and joint developed the pain in the jaw declined. On May 22nd the junctions of the ribs with the costal cartilages became swollen and very tender, and the patient also complained from time to time of aching pains in the shoulders. The joint is less swollen; the ribs are less tender just now. I have referred to the case as a good illustration of what I want to prove—viz., that irritation about the root of the fifth nerve will also sometimes give rise to modifications of nutrition in the ends of the bones or about the joints.

---

[4] Gaskell: Journal of Physiology, vol. iii., p. 18.

[5] Foster's Physiology, 4th edit., p. [illegible]

Lastly, with regard to chorea. It is not difficult to see that, if the power of the vaso-motor fibres has been weakened, an irritation at the root of the fifth nerve may by radiating through the Gasserian ganglion or Meckel's ganglion, which are in connexion with the carotid plexus—a superior branch, that is, of the upper cervical ganglion—cause vascular dilatation and perivascular change in the track of the middle cerebral artery, and that these changes would produce the incoördinated movements of chorea. Dr. Dickinson has made out very clearly that it is in these parts and in the posterior and lateral parts of the grey matter and in the upper portions of the cord that vascular dilatation and perivascular change take place both in chorea and diabetes; and I venture to suggest that they are induced in the manner I have indicated.

NOTES OF VISITS TO CONTREXÉVILLE AND ROYAT-LES-BAINS.

BY F. R. CRUISE, M.D. UNIV. DUB.,

PRESIDENT OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

(Concluded from page 1123.)

BEFORE concluding, I should like to add some notes of a visit which I paid to Royat-les-Bains in June, 1884, and of the circumstances which brought me there.

One day, in the spring of last year, I happened to complain to my friend and colleague, Dr. Patrick Hayes, about the great annoyance I had suffered from eczema. This affection, presumed from many special symptoms to be of a gouty nature, had been treated in various ways, but with very partial success. Dr. Hayes told me that a patient of his, very similarly affected, had been sent by a London physician to Royat-les-Bains, and had been effectually cured. A few inquiries satisfied me that this mineral watering-place enjoyed a well-merited celebrity in the treatment of chronic forms of gout, and I felt that it was well worth my while to pay it a visit. Accordingly to Royat I went in June, 1884, and, to make a long story short, I was cured so completely that with a little attention to diet, and some other hygienic details, I have escaped ever since all annoyance from my troublesome ailment. It is but truthful to add that I have kept up the use of the waters, and observed the rules of life laid down for me. Many patients who are careless about these matters blame very unjustly the remedy which they unreasonably expect will cure them despite of themselves. Anyone who has undergone for years the indescribable worry of eczema will understand that I naturally feel very grateful to Royat, and am anxious to make known to the members of the Academy of Medicine in Ireland some details concerning it.

Leaving Paris by the Lyons Railway, a journey of some nine hours brought me to Clermont-Ferrand, the wealthy capital of the Auvergne district, and in ten minutes more I arrived at the picturesque village of Royat-les-Bains, one of the most celebrated mineral stations of France. Once settled in my hotel (Chabassière's), which it is but just to say combined every comfort with moderate charges, I sought the advice of Dr. Alexandre Petit, whose *brochure* on Royat I had already studied. Under his guidance I commenced the course, which lasted three weeks. The routine was much as follows:—At 7 A.M. I took a glass of the Eugénie water hot from the spring, then a reclining bath in the same water at a temperature of 95° F. After the bath I had another glass of the water. Then I returned to my hotel, and had coffee and strawberries. At one o'clock *déjeuner à la fourchette*; at 4 to 5 P.M. two glasses of the St. Mart spring, with fifteen minutes between; at 6 o'clock dinner. Thus I passed the days, spending the leisure intervals in exploring Royat and its environs, and in observing the use and effect of the waters. Day by day I improved in health and spirits, the eczema cleared off, and no new spots appeared. As already stated, I have remained well now just a year.

Royat-les-Bains is a village, consisting mainly of the *établissement* for the waters and baths, the hotels, boarding-houses and villas, which accommodate the visitors in the season, from May till the end of September. It is beautifully situated in the Auvergne mountains, about 1500 feet above the sea level, in a valley stretching from the base of the Puy-de-Dôme to Clermont-Ferrand, and following the course of a torrent of lava which at some remote age poured down from the neighbouring volcanoes, now completely extinct. The lowest portion of this valley conveys the Tiretaine, a mountain stream of some considerable size. All that a lovely country, an agreeable bracing climate, a wealth of interest, historical, geological, and botanical, combined with health-giving waters, can offer to satisfy the visitor will be found in plenty at Royat-les-Bains. To those who love mountain scenery as I do, no day spent there can feel irksome or tedious. It is right to add that it is a very quiet spot, to which the world of fashion has not yet penetrated; but its fame is of old standing, it is thoroughly appreciated by the medical faculty and people of France, and is yearly becoming better known to the world at large.

To prevent confusion about names, let me observe that Royat, the original village, is situated about fifteen minutes' walk higher up in the valley than Royat-les-Bains, and, though most interesting to visit, is not the mineral station known as Royat. The original village is evidently of great antiquity, resembling a miniature old Roman town. The photographs which I exhibit, many of which I took myself on the spot, show the curious old streets in which it abounds, and the castellated and battlemented church, a Romano-Byzantine edifice, dating from the twelfth century. There are clear evidences that the ancient Romans knew Royat well, and used its hot springs, both for separate baths and for the piscine or general swimming tank. Just below the railway bridge may be seen the remains of Roman baths and piscine, close to the St. Mart Spring, which were discovered in 1843. These are some of the many ruins which prove the Roman occupation of Royat in ancient times. The entire neighbourhood of this station abounds in interesting places, which serve to occupy the leisure hours of visitors to the waters.

Clermont-Ferrand, to which I have already alluded, is a little over a mile from Royat, and may be reached by omnibus in about ten minutes. Expeditions are made thither almost daily, and I know no more agreeable stroll than to wander through its beautiful Gothic cathedral, and then walk down to the Place Pascal, in which we find the statue of the great philosopher, so placed as to look to the distant towering Puy-de-Dôme, upon the heights of which he performed the experiments which led to such advance in barometric science. Selecting a clear day, a journey of some two hours and a half brings to the summit of the Puy, with its ruined Temple of Mercury, now replaced by an observatory, from which a magnificent view of the surrounding country stretches out on all sides. In every direction about Royat we find beautiful mountain passes through which to ride, drive, or walk; picturesque old towns and villages, and ruins of ancient castles and châteaux. Not a day of the whole course of three weeks need pass without a pleasant excursion amid scenery lovely enough to please every eye, and monuments of the old feudal times, like Tournoël, grim and gaunt enough to make one rejoice that we do not live in such wicked and awful days of savagery. I shall not attempt to enumerate the various points of interest around Royat, as the local guide-books offer all needful information, and I only allude to them here to illustrate the attractiveness of the place.

Let us now see what the waters of Royat are, what is their nature, and in what diseases they may be used with benefit. There are four springs, which much resemble each other, though differing in certain details[1]—namely, the Eugénie, the César, the St. Mart, and the St. Victor.

Taking the Eugénie spring as the one both typical and most important, let us examine its constitution. I append M. Lefort's analysis:—

Eugénie Spring (Temperature 95° F.).

Bicarbonate of soda	1·349
" potash	0·435
" lime	1·000
" magnesia	0·677
" iron	0·040
" manganese	traces
Sulphate of soda	0·185
Phosphate of soda	0·018
Arseniate of soda	0·004
Chloride of sodium	1·728
Iodide and bromide of sodium	traces
Silica...	0·156
Alumina and organic matters	traces
Chloride of lithium	0·037
Total solids	5·623
Free carbonic acid...	0·377

From the foregoing table it will be seen that this spring belongs to the class of alkaline-chlorinated waters, with the addition of salts of lithium, iron, and arsenic. The effects, used internally, may be surmised from its composition. It is stimulating to the circulation, diuretic, laxative, and tonic. The diuretic effect is the most manifest, often doubling the quantity of urine excreted, and at the same time raising the specific gravity one-third or more. In its diuretic properties I observed a strong similarity to our own mild sulphur water at Lisdoonvarna, which, although quite different chemically, is famous also for the cure of gouty and cutaneous affections. The laxative effect of the Eugénie water is mild, but unmistakable, the sulphate of soda mainly accomplishing this end. The tonic properties, due to iron and arsenic, are very pronounced, and, together with the chlorides, serve to mark the difference between Royat and the stronger and more purely alkaline springs, such as Vichy, Vals, Pongues, and others, indicating, moreover, their greater suitability for lymphatic and debilitated patients. In fact, for strumous subjects no waters, excepting alone those of La Bourboule, which is quite near, enjoy an equal reputation. At some future time I hope to bring La Bourboule under your notice. As already stated, the four springs of Royat, although resembling each other, differ in certain points. Thus we have seen the composition and effects of the Eugénie spring.

The César is the least mineralised of all these waters, but is very agreeable and piquant in flavour, and is found very useful in dyspepsia. It stimulates the mucous membrane of the stomach, improves the appetite, helps digestion, and increases the flow of bile and urine.

The St. Mart water contains a considerable quantity of chloride of lithium, and is particularly suited for gout and rheumatism and all allied affections.

The St. Victor spring is richest in iron, and is specially useful for anæmia, diseases of females, and for the weak and debilitated.

All these springs are used, according to the necessities of the case, in three different ways: first, internally; secondly, externally—as baths, reclining or swimming (piscine), and douches; and, thirdly, by inhalation while in a state of pulverisation or minute division. It is easy to see that with such a repertory of potent agents as these thermal waters afford, a judicious physician wields immense therapeutical power.

Let us now briefly enumerate the principal diseases in which they may be used with advantage. These may be divided, for practical purposes, into three great classes:—

1. *All forms of gout and rheumatism*, especially the atonic phases. It is almost needless to say that a mild alkaline water, modified by chloride of lithium and ferro-arsenical salts, is certain to benefit this class of ailments, and accordingly we find them improving from day to day at Royat, including gouty and rheumatic affections of joints, muscles, fasciæ, nerves, skin, especially eczema, gouty dyspepsia, gastralgia, asthma, and so forth.

2. *Anæmic and lymphatic affections.*—The combination of chloro-alkaline waters with iron and arsenic improves the appetite and digestion, and speedily reconstructs the blood in anæmia. It is found very useful also in atonic dyspepsia, and in all the nervous troubles appertaining thereto. For insomnia Royat enjoys a special and most favourable reputation.

3. *Affections of the throat, lungs, and uterus.*—The utility of the waters of Royat in this third class of ailments is what we might expect from the strong similarity between them and the waters of Ems—Royat being, in fact, the French counterpart of Ems, enjoying, however, the great advantage over the latter of a climate both bracing and tonic, in place of relaxing and debilitating. Accordingly, we find chronic affections of the larynx and pharynx, bronchial catarrh, asthma, and even the earlier stages of pulmonary phthisis, improving at Royat, and the crowds which frequent the inhaling rooms give proof of the beneficial results felt by all who resort to this form of medication. Chronic affections of the uterus are likewise found to derive immense service from these waters.

For myself, I am strongly disposed to believe that the efficacy of the waters of Royat are greatly augmented by the climate, which is, like all mountain air, revivifying in a marked degree. It is, moreover, temperate and dry, and its salubrity is proved by the abundance of fruit and flowers for which the whole district is celebrated. I shall not dilate further upon the virtues of Royat, trusting that I have already given a sufficiently clear outline to enable my hearers to select the cases best suited for the use of its waters.

I have to thank you, gentlemen, for the patience with which you have listened to me this evening. My earnest conviction of the great value of the waters of Contrexéville and Royat-les-Bains is the best excuse I can make for trespassing so long upon the attention of the Academy of Medicine in Ireland.

ON THE

TREATMENT OF BRONCHIAL ASTHMA AT MONT DORE, FRANCE.

BY DR. EMILE EMOND,
CONSULTING PHYSICIAN, MEMBER OF THE CLINICAL SOCIETY OF LONDON.

I PURPOSE in these few lines to extend to England the reputation of Mont Dore springs which has been long established in France, and to point out to the medical profession their powerful resources in the treatment of bronchial asthma.

Asthma is a capricious disease, having varieties and the most numerous forms, of which physicians have not yet given an accurate definition nor found out the medicine to cure it in spite of modern researches. We are amply provided with numerous remedial means, but the results are not always as precise as we could desire. "Asthma is an independent and essential disease, purely dynamic in nature, and not necessarily connected with any pathological lesion" (Thorowgood). It is spasmodic or catarrhal; but, whatever may be its form, G. Sée describes it as compounded of three elements: "a special intermittent dyspnœa, a bronchial exudation, and a secondary emphysema." Dyspnœa is the characteristic element; its form is always the same; its intensity only varies. On the contrary, catarrh may be of all forms; it appears in one with profuse running expectoration, clear, glairy, frothy, and pearly; in another the sputum is peculiar, scanty, viscid, thick, and yellow. The one has commencing catarrhal asthma; the other [illegible] dyspnœa. Trousseau regarded asthma as a diathetic neurosis. G. Sée appears to have regarded it as essentially due to a modification of blood or to a constitutional vice of nutrition of the tissues, as gout or dartre. Guéneau de Mussy believed the arthritic diathesis to be the essential cause of asthma. The seat of nervous spasm is not yet fixed. Trousseau thinks that it is laid in the Reisseissen muscles; G. Sée in the inspiratory muscles and diaphragm. There are only a few diseases that can be confounded with asthma, if we consider that it is distinguished from all dyspnœas, the organic diseases of the heart, and pulmonary tuberculosis by its characteristic signs, its periodicity, the form of its attacks, and the bronchial catarrh which accompanies it.

---

[1] It is important to know that these waters bear carriage remarkably well, and lose little in the process.

Whether caused by diathesis or inflammation, asthma is sometimes cured at Mont Dore. But the variety which is most often met with there, and is treated with the greatest success, is catarrhal bronchial asthma, or humid asthma. In this form, attacks, at first separated, meet; the dyspnœa increases and becomes continuous in consequence of the viscidity of bronchial exudation. But as soon as the particles of phlegm can be ejected and air begins to penetrate into vesicles, emphysema diminishes, hæmatosis takes its course and relief arrives. As to the spasmodic dry asthma, which is hereditary and met with in all ages, it obtains there a manifest relief and sometimes a real cure.

It is well known now how many therapeutical means we have at Mont Dore, and physicians are aware of their effects. They vary according to the constitution, age, and sex of the patient. We can modify dyspnœa, bronchial exudation, and emphysema. Our waters in a variety of ways can be sedative, excitant, derivative, even substitutive, according to the mode of application and the duration of the treatment.

First, water is taken as drink; it gives an increase of action to the nutritive functions and to circulation.

Next, the inhalation of vapour, the special action of which on the respiratory organs is a well-established fact. Experience has proved that it is the most valuable remedy for bronchial spasm; that mineral vapour has an effective sedative action on smooth and elastic muscular fibres; and that it affords an instantaneous relief. Invalids stay in the vaporarium during a time varying from fifteen to sixty minutes, according to the case.[1] I think that sedative action is due in great part to vaporised arsenic and carbonic acid.

After the half-baths of the Pavilion at 111° F. they are given according to the constitution of the invalids, and produce wonderful effects. On leaving this bath, which lasts from five to twelve minutes, a feeling of comfort succeeds almost immediately to the general excitement, the body is covered with perspiration, and the breathing returns to its normal condition.

At last, the spinal douche, which has been largely used at Mont Dore, stimulates the vaso-motor nerves, re-establishes the skin functions, and produces the best results.

A sedative influence, I dare say, is one of the most evident and immediate effects of the Mont Dore treatment. It is observed with the most irritable subjects, re-establishes the disorders of innervation, influences general circulation, and chiefly the respiratory apparatus. Nervous spasm is alleviated. These results are specially observed in essential spasmodic asthma, where neurosis seems to be attacked in its own origin—that is to say, in the morbid spasmodic element.

Mont Dore waters have a local resolvent action, chiefly upon the mucous membrane of the respiratory organs, which is modified by their direct contact. This first effect upon the lungs is particularly observed in catarrhal bronchial asthma. I compare it to the effect of digitalis on the heart. All these phenomena produce a reconstituent action of the organism, shown by the development of the appetite, re-establishment of the digestion, equalisation of the circulation, return of the skin functions, and increase in strength.

If, now, there be in the action of these waters something specific, it is necessary to try to point out, amongst their numerous mineral principles, that which may be the agent. I believe that it is mainly the arseniate of soda, notwithstanding the small proportion in which it enters into the composition of the waters of Mont Dore. This was Thénard's opinion, since he says in his note to the Académie des Sciences, "One cannot doubt that it is to the presence of arsenic that one ought to attribute the powerful action of this water upon the animal economy." A most valuable remedy for asthma is found in the various preparations of arsenic. Indeed, arsenic modifies powerfully the nutrition.

To illustrate now what has been said, I relate the following two cases.

CASE 1.—Miss W——, aged about thirty, was sent to me last July at Mont Dore, from London, where she lives. No family history of asthma; her mother is gouty, father and sister healthy. Her face is pale and worn, no emaciation, but very reduced in strength; she cannot walk at all, and on arriving she had to be taken up to her bedroom by servants. In September, 1880, this lady had for the first time an attack of severe bronchitis; she passed through the winter at Pau, where she had a relapse. In the spring of 1882 severe spasmodic asthma associated with urticaria developed itself. She had once an attack of herpes. She has been troubled with fits of asthma during the last two years, and is worse in damp weather; always has some amount of dyspnœa, but the attacks come on in the evening with sense of tightness across the chest, and go off with cough and frothy expectoration. When in bed she is obliged to sit up. Many remedies appear to have been fully tried without any great benefit: iodide and bromide of potassium, arsenic, citrate of caffeine, and occasionally apomorphia, also some anti-asthmatic cigarettes whenever an attack was threatening. The fits of asthma come on in an ingravescent way at any time of day or night. On examination the chest was fully resonant under both clavicles, very feeble inspiratory murmur, with prolonged expiration over the chest; sibilant and sonorous râles are audible on both sides. The action of the heart is feeble but regular, pulse weak, tongue moist, no appetite. On July 24th she began treatment. I first advised her to drink every day half a glass of the Madeleine water, to stay a quarter of an hour in the aspiration room, and to take a foot-bath for six minutes at 4 P.M.—25th: Worse, fit of asthma next night, she could not continue the treatment the next day.—27th: Began again the same treatment; no asthma in the evening, she slept for a few hours. Continued every day increasing gradually the duration of inhalation of vapour; fit of asthma almost every night, but less severe. In a week's time the relief to all the symptoms was most remarkable. On Aug. 4th she could stay for forty minutes in the aspiration room, fits of asthma were less and less severe, expectoration easier. My patient began to eat and walk into her sitting room. On August 6th, I prescribed a spinal douche for six minutes at 94° F., no inhalation this day. A fit of asthma more severe next night.—8th: Two half glasses of water, another douche for six minutes; no asthma, she slept during four hours. I continued the douches every other day, alternating with inhalation of vapour and increasing the drinking with half a glass of water, and she had but one fit till the twenty-first day of the treatment. In this interval she got appetite, strength had returned, dyspnœa had improved; Miss W—— was able to get up by herself to her bedroom, and to walk in the park. She was allowed to rest for a fortnight, and afterwards began again another course of treatment of fifteen days. Every morning she stayed for forty-five minutes in the aspiration room, she took a half bath of six minutes at 104° F. at the Pavilion, alternated every other day with a spinal douche of five minutes. At the end of this treatment, my patient declared herself free from difficulty in the breathing, free from nocturnal fits, and cured. In fact, her strength had returned, she had gained in weight. In last February I saw her in London, looking stout and healthy. She had persevered, as I had prescribed, for some weeks with the Mont Dore waters, and she never got either cold or asthma, nor had she needed any treatment since she left Mont Dore last September.

CASE 2.—Mrs. B——, aged forty-five, living at Carlisle, came to Mont-Dore in July, 1884. Been liable to asthma for fifteen years; at times she was free for some weeks of all breath-difficulty. There is no history of gout or rheumatism in the family, nor any skin-disease. During the winter of 1883 Mrs. B——'s breath difficulty increased greatly; she went to Cannes to seek relief, but dyspnœa came on in an ingravescent way; she gradually got worse. On examination, patient has an extra-resonance of the chest; inspiration is difficult and noisy; expiration prolonged, with wheezy râles. Enlargement of liver; heart sounds weak and muffled; urine loaded with lithates; tongue moist. She complains of difficulty of breathing, cough, and copious glairy expectoration, obliging her to sit up at night. She is not able to move without suffocation. I prescribed as treatment every morning two half-glasses of the Madeleine water, thirty minutes of aspiration of vapour, a foot-bath for six minutes, and a half bath of the Pavilion at 105° F.

---

[1] These various processes are described in detail in my small work on Mont Dore and its Mineral Waters, published by Wyman and Sons, Great Queen-street, [illegible].

every second day. This medication, well supported, was followed up for a week. Breathing appeared already easier, expectoration was less copious, and Mrs. B—— was able to walk a little in her bedroom. After a fortnight of the same treatment she persevered with three half-glasses and the half-bath of the Pavilion alternated with a spinal douche of six minutes. From this time oppression diminished greatly, strength returned, and Mrs. B—— felt well enough to go downstairs without help, and to be discharged. After a course of treatment of twenty-eight days she was able to walk a long time in the Park; dyspnœa had ceased; expectoration disappeared.

I think both these cases show the great importance of the aspiration of the mineral vapours, and of the use of the spinal douche in bronchial asthma.

ON A CASE OF THYROIDECTOMY.

BY THOMAS H. MORSE, F.R.C.S.,

ASSISTANT-SURGEON TO THE NORFOLK AND NORWICH EYE INFIRMARY, AND TO THE NORWICH JENNY LIND INFIRMARY FOR SICK CHILDREN.

THE subject of removal of the thyroid body having been lately under discussion, the following case which occurred in my practice may prove of interest.

The patient, a young woman aged twenty-two, six years ago first noticed a small swelling on the left side of the larynx, which gradually increased in spite of numerous remedies. From the time of its first appearance she suffered occasionally from attacks of dyspnœa. In 1881 she was in the Norfolk and Norwich Hospital, where, she says, the tumour was tapped, but no fluid came out: it was afterwards injected with iodine on several occasions. In the following year she was under the care of Mr. Hutchinson in the London Hospital. During all this time the tumour was gradually enlarging. In February, 1883, I first saw her, and from then till the date of operation it continued to enlarge, and the symptoms became more aggravated. In March, 1884, I sent her to London to consult Mr. Symonds of Guy's Hospital as to the advisability of removing the tumour; he recommended her to submit to the operation. The tumour at this time formed a considerable prominence below the chin, and extended from the level of the hyoid bone down into the chest behind the sternum; it occupied the whole of the centre and left side of the neck, displacing the various structures to either side; its surface was covered with a plexus of veins, and the omo-hyoid muscle from the left side was stretched obliquely across it. It was also partly covered by the lower attachments of both sterno-mastoid muscles, and the larynx was pushed over to the right side of the neck, so that the pomum Adami was situated close below the angle of the jaw. The left carotid artery could be felt pulsating quite superficially along the posterior border of the sterno-mastoid muscle. This displacement will be best understood if I mention that the distance between the thyroid cartilage and the left carotid artery, measured horizontally, was four inches. The upper part of the tumour was quite movable laterally, but its lower end was more tightly fixed in the upper aperture of the thorax. She could only walk slowly and had to keep stopping to get breath, as the least exertion brought on difficulty of breathing. On several occasions she suffered from attacks of dyspnœa lasting about an hour, during which time the face was livid, and she herself, as well as those around her, thought that death from suffocation was impending. Inspiration was prolonged even when sitting still. She also suffered from a constant dry laryngeal cough. The function of the œsophagus was not interfered with. Her general health was otherwise good, except that since I have known her she has been gradually getting thinner, her weight at the time of the operation being six stone and a half.

On April 4th, 1884, having made arrangements for the operation, I had the assistance of the following gentlemen: Dr. Firth, Mr. Donald Day, Dr. Doyle, and Mr. Pollard. Using the steam carbolic spray and other antiseptic precautions, an incision in the skin, five inches in length, was made from the hyoid bone to the sternum, over the most prominent part of the tumour. A plexus of veins covered the anterior surface of the tumour; these were divided one by one between two ligatures, notwithstanding which there was considerable loss of blood, and besides ligatures, six pairs of Sir Spencer Wells' artery forceps were in constant use. This part of the proceeding was somewhat tedious, as it seemed almost impossible to control the hæmorrhage. The tumour was enclosed in a more or less distinct capsule, which was not very easily separated in front, and appeared part and parcel of the tumour, doubtless owing to the iodine injections. The sides of the tumour were less firmly adherent and more easily separated with the finger. During all this time there was a general oozing of blood both from the capsule and from the surface of the tumour. Having first separated the upper end of the tumour, I was enabled by drawing it down, to tear it off from the pharynx and œsophagus, which formed the posterior boundary, the capsule being hardly distinguishable here. The lower end of the tumour extended down behind the sternum into the chest, and after its removal, the bottom of the cavity left was bounded on one side by the whole length of the innominate artery, on the other by the left common carotid artery from its origin upwards; these could be distinctly felt pulsating and apparently naked at the bottom of the wound. The left inferior thyroid artery was torn across, and severe hæmorrhage occurred from it. No distinct isthmus was seen, although from the situation of the tumour and the way in which the various structures were displaced I believe that the part removed represented the enlarged left lobe of the gland, in which case the right lobe was in all probability left *in situ*, not being abnormal in size. She had by this time lost a large quantity of blood, and was very faint. I therefore administered a subcutaneous injection of ether, after which the pulse improved. As many as twenty-four ligatures were used. The operation took an hour and a half. The parts returned easily to their natural positions; the wound was united with silver wire sutures, a drainage-tube having been inserted at the lower angle. The dressing consisted of green protective, iodoform gauze, Gamgee's absorbent tissue, a sponge compress, the whole being kept in position by a bandage. The tumour measured six inches in length, three and a half in breadth, and weighed fourteen ounces. It felt very firm, and was solid throughout except at one point, where was a small cyst containing about half an ounce of bloody serum. Mr. Symonds has kindly made a section of it for me, which shows the structure very beautifully. It consists of a stroma of fibrous tissue, containing large vesicles, lined with a single row of epithelium and containing in their interior a gelatinous so-called colloid material; some of these vesicles are larger than others. There are also to be seen a large number of small spheroidal cells of different sizes, which seem to be in a state of rapid proliferation, these, together with numerous bloodvessels, which can also be seen, would indicate a steady increase in size of the whole tumour, which corresponds with the clinical history.

The patient was much exhausted by the operation: her face and hands appeared perfectly bloodless, the pulse rapid and feeble; however, she slept at intervals during the night, and took a considerable quantity of liquid nourishment. For the first few days after the operation there was a large quantity of discharge, consisting chiefly of bloody serum. Twenty-four hours after the operation she complained of considerable pain when swallowing, and down behind the sternum, also in the back behind the shoulder-blades. At this time also the temperature rose steadily to 103°; the pulse was 120 per minute; she was extremely weak, and I began to fear suppuration in the mediastinum. During the following night an ice-bag was applied to the neighbourhood of the wound, and one of Leiter's leaden coils to the head; through this latter a stream of iced water was kept constantly running. She experienced the greatest relief from this treatment; the pain in swallowing diminished, and by the next morning the temperature had fallen to normal, and a severe throbbing pain in the head much lessened. By the third day her pain in swallowing had greatly diminished, and from this time her convalescence was uninterrupted. I never knew a patient to take such enormous quantities of liquid food, so much so that by the tenth day after the operation her diet had reached the following amount in twenty-four hours: Twelve eggs, twelve pints of milk, three pints of beef-tea, half a bottle of port wine, two ounces of brandy, three oysters, and a small tin of Brand's essence. On the twentieth day after the operation she had so far recovered that I was able to move her into the country to complete her convalescence, as she was much worried by the constant noise in the town. The upper four inches of the wound healed by primary union, but the remainder was not soundly healed until the end of seven weeks, as a deep sinus continued to discharge pus apparently from behind the trachea. By degrees the superficial veins began to appear and the colour returned to her face, and in two months from the time of operation she had gained in weight two stone, which she has maintained ever since, and is, I suppose, her normal weight when not interfered with by the presence of the tumour.

There is one very interesting point at the present time occupying the attention of surgeons, which is the probability *of the occurrence of symptoms resembling myxœdema following* the complete excision of the thyroid gland. Sir William Mac Cormac, in his address on Surgery, delivered at Belfast in 1884, has given a very complete summary of our state of knowledge up to that time on this subject.

The patient was exhibited before the East Anglian Branch of the British Medical Association in October, 1884, and also before the Norwich Medico-Chirurgical Society in March, 1885, up to which time she remained in good health, and showed no signs of any evil effect following the operation.

Norwich.

A CASE OF SO-CALLED CATHETER FEVER.

By GEO. C. MACDONALD, M.R.C.S., L.R.C.P.,
LATE RESIDENT PHYSICIAN, ROYAL EDINBURGH INFIRMARY.

THE following case is of interest insomuch as it shows that some at least of these so-called cases of catheter fever are septicæmic in origin, and therefore, to a certain extent, capable of control.

James M——, aged fifty-five, a factory hand, was admitted into the Royal Edinburgh Infirmary for hæmaturia and frequent calls to micturate. His present illness commenced as a severe pain in the left lumbar region ten weeks before admission, for which he can assign no cause. *The pain commenced on micturition, but subsided* towards the close of the act. The desire was so great that he was forced *to pass his urine, on an average,* every hour and a half. The urine was clear, there being no blood or thickness noticeable. At times he would have a severe pain shooting down into the left groin and testicle, accompanied with a distinct rigor. This condition continued for fourteen days, when the desire to micturate became so aggravated that he was forced to seek relief every half hour. Eight weeks after his first attack of pain it suddenly left him, and he now, for the first time, noticed that his urine became tinged with blood towards the last few drops, accompanied by a severe scalding pain in the penis, but there was no pain on exercise. The blood now increased in amount until the *urine became as black as* porter. *He had been under treat*ment for the last two months, but his medical man advised him to seek further advice. The family and personal history is good.

His present condition is as follows: Confined to bed, general development and muscularity fair; height, 5ft. 8½in.; weight, 10st.; temperature 98° to 99°; complains of slight sweats; skin soft and normal in colour; lungs normal for age. Genito-urinary system: Urine, dark, due to admixture of blood; reaction acid; sp. gr., 1009 to 1010; deposit of urates; amount varies from 90 to 100 ounces in the twenty-four hours; albumen present, due to the blood. The microscope reveals a great number of blood-discs and some amorphous urates; no germs or pus cells. Micturition is about *every hour, accompanied with slight* pain in the left lumbar region, where there is tenderness on pressure. The pain at times radiates to the testicle and end of penis. On rectal examination the prostate is found to be slightly enlarged. Diagnosis: Nephritic calculus probably passed into bladder.

March 8th (two days after admission): The hæmaturia is the same as when admitted. There are no casts nor any renal epithelium or organisms.—18th (twenty days after admission): The patient shows slight improvement, there being less blood. There is a little pus in the urine to-day; he complains of great pain at the end of the penis after micturition, also at the neck of the bladder; he cannot hold his urine longer than half an hour; no organisms.—19th: The patient was seen to-day by a surgeon, who thought perhaps the calculus from the kidney had been passed into the bladder; consequently he submitted the bladder to an exploration with Teevan's sound; but on attempting to withdraw the urine through the sound it was found that the plug was so fixed that *it could not be removed.* He therefore passed a red rubber catheter anointed with 1 in 20 of eucalyptus and olive oil. The patient was given immediately afterwards five grains of quinine and thirty grains of bromide of soda. No stone could be discovered.—20th: Temperature this evening went up to 99·4°; no rigor or any sensation of chilliness; pulse 60 (full); amount of urine passed sixty ounces; more pus and less blood than yesterday.—21st: This evening the temperature went up to 103·2°. The patient complains of great thirst; *amount of urine passed fifty* ounces; *pupils normal*; *no* nervous phenomena; pulse 96; micturition less frequent.—22nd: Temperature this morning 102°; at noon 102·8°; at midnight 101°. Urine examined at bedside, immediately passed into a clean vessel, shows as follows: reaction alkaline, smells fetid. By microscope a large amount of pus cells, a few red cells, and many rod-shaped bacteria. Ordered five grains of sulphate of quinine with fifteen grains of benzoate of soda, every four hours. Water removed from bladder by syphon action. Less urine has been passed to-day. Ordered fomentations over loins and bladder.—23rd: Temperature this morning 100°. Says he feels better; not so thirsty; urine not so fetid, and contains less pus. He, however, sweats profusely, but has passed a better night, being in less pain. *No action of bowels.* Ordered colocynth with hyoscyamus pill (ten grains) at bed-time.—24th: Temperature: morning 99·8°; evening 101·4°. Sweats continue. Urine still contains rod-shaped bacteria. Amount passed 100 ounces. Bowels moved three times.—25th: Temperature 97·4°, showing a marked fall; evening 99·4°. Amount of urine sixty ounces. Less pus; still fetid and contains bacteria. Sweats still present. Bowels moved once.—26th: Temperature 99°. Amount of urine 100 ounces.

April 3rd.—The state of the patient's urine is much improved as regards bacteria, which, however, are still present, the urine continuing to be alkaline in reaction. He still complains of the old pain in the left lumbar region under cataplasm liniment to loins.—4th: The old pain is *still complained of this morning. In other respects he is in statu quo.*

Remarks.—My term of office having expired, I lost sight of the patient, but I believe he left the hospital very much in the same condition as in the last report, the germs still remaining. The presence of the bacteria in the urine I believe to have been due to the employment of Teevan's sound, the interior of the instrument being probably dirty, and consequently loaded with septic germs. I think that this case plainly shows that the proper treatment of these septic bladder conditions is the drainage of the viscus by the syphon action, thus removing the major part of the bacteria, followed by large doses of quinine and benzoate of soda, in the hope of lessening the alkalinity of the urine, and with the hope of thus bringing about the death of the germs. Lastly, that fatal terminations may be looked for in such cases without probably much organic change in the kidneys, the cause of death not being uræmia, but septicæmia.

Duchess-street, W.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prœmium.

ST. THOMAS'S HOSPITAL.

COMMUNICATION BETWEEN SMALL INTESTINE AND BLADDER; TUBERCULOSIS; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. CROFT.)

FISTULOUS communication between the bladder and the intestinal tract above the rectum is usually the result of malignant ulceration which has extended from the sigmoid flexure into the bladder. Tubercular ulceration rarely produces such a condition. *In this case the local signs were* very few and the absence of chest symptoms, although extensive tubercular disease of the lungs, was found post mortem, rendered exact diagnosis difficult.

For the following notes we are indebted to Mr. W. F. Ward, dresser.

John R——, aged sixty, a wine cooper, was admitted under the care of Mr. Croft on February 4th and died on February 27th, 1885. Family history: Parents both died at the age of seventy-four, cause of death unknown. The father suffered from rheumatism. Three brothers and one sister healthy. No history of phthisis or malignant disease. Until six weeks before admission, when he first felt pain on micturition, he had always been healthy. He had not had gonorrhœa and had never passed gravel. Pain was felt at the commencement of the act of micturition. The stream of urine was smaller than formerly, and he says that it sometimes stopped suddenly. A month ago the urine became thick with sediment and of a port-wine colour. Lately micturition had been very frequent, about twenty times in the night. He had lost flesh rapidly, about two stone in the six weeks.

The patient, an emaciated man, with sallow complexion and dilated capillaries in the cheeks, complained of frequent and painful micturition. The abdominal walls were lax and there was no tumour to be found, percussion eliciting a tympanitic sound all over. There was tenderness in the region of the bladder but no pain. There was a small ventral hernia. Urine, sp. gr. 1019; slightly acid. It contained no albumen; it was thick, of a brownish-yellow colour, and deposited a copious sediment. Microscopically, pus, blood-corpuscles, and vegetable fibres were seen. Tongue was dry, and he was thirsty. Pulse about 80, full and compressible. Morning temperature 98·8°; evening 102·2°.

Feb. 6th.—The patient feels well, and has no pain except when passing urine. Appetite very fair. He does not sleep well.

8th.—He complained of discomfort in the abdomen, which disappeared after the administration of an enema. He was sounded under ether, but no calculus was found.

10th.—Feeling rather better and able to retain urine for a longer time. Urine, sp. gr. 1016; very offensive in odour; other characters similar to those found on admission. The abdomen had flaccid walls. There was no distension and no tenderness on palpation. No tumour could be felt on palpation.

13th.—A mixture containing dilute sulphuric acid, tincture of opium, tincture of perchloride of iron, and infusion of calumba was ordered.

20th.—Urine passed in smaller quantity. There has been an evening rise of from one to two degrees since admission, the morning temperature being usually about 99°.

22nd.—Diarrhœa; frequent, loose, yellow, and offensive motions commenced and continued until his death on the 27th. The bowels acted from six to eight times in the twenty-four hours, there was much hiccough and loss of appetite, and very little urine was passed. During the last few days he became restless and delirious, on the day of his death the skin becoming cold and clammy. Pulse 128; temperature 99·4°. After the 20th there was no rise of temperature above 100° nor fall below 98·4°. He had emaciated greatly. During the whole of this time there had been no cough or symptoms of lung disease.

Necropsy, made on the following day by Dr. HADDEN.—On opening the abdomen the small intestines were adherent to each other by organised lymph, but were separable on slight traction. No tubercles were seen. At the points of contact there were longitudinal red streaks. There were dots and lines of pigment scattered over the peritoneum covering the small gut. On removing the viscera from the abdomen a fistulous communication was found between the ileum and the bladder, both parts being pretty firmly adherent. In the portion of ileum examined typical tubercular ulcers were found, fairly extensive near the ileo-cæcal valve. On the [illegible] there were solitary miliary tubercles. The [illegible] raised and thick, and the ulcers did not extend [illegible] beyond the mucous coat, excepting in the neighbourhood of the bladder, where some had penetrated into a cavity situated near the summit of that organ, which again communicated with the bladder by a small opening. The cavity just mentioned was formed by intestine, bladder, and surrounding semi-organised lymph. Pleuræ firm and extensively adherent on both sides. In each lung mixed broncho-pneumonic and tubercular disease, distinct miliary tubercles [illegible]. There were also old caseous nodules. Other organs fairly healthy.

Remarks.—This man was admitted under Mr. Croft's care for cystitis. A local cause for that condition was carefully sought for, but none was discovered. In the course of a few days feculent matter appeared in the urine, and the nature of the case became less obscure. As no consistent feculent material troubled the bladder or was perceptible, and as the starch and vegetable tissues when examined microscopically were not in an advanced stage of digestion, it was inferred that the small intestine had opened into the bladder. Whether this ulceration had been the result of a cancerous or tubercular new growth there was no positive evidence; indeed no tumour could be traced. Clinically and pathologically the case is one of interest, and worth recording.

DUNDEE ROYAL INFIRMARY.

MALIGNANT ENDOCARDITIS FOLLOWING A SLIGHT INJURY TO KNEE; DEATH WITHIN FOURTEEN HOURS OF ADMISSION; NECROPSY; REMARKS.

(Under the care of Dr. SINCLAIR.)

DURING the present year a great deal of attention has been given to the disease known as ulcerative endocarditis, and from time to time we have published cases in the "Mirror" (Jan. 13th and March 21st). We would refer also to the lectures by Dr. Osler published March 7th, 14th, and 21st.

For the clinical record of the following case we are indebted to Mr. W. Gibb, medical assistant; and for the notes of the post-mortem examination to Mr. A. M. Stalker, M.A., M.B., pathologist.

G. B——, aged twelve, was admitted at 5.30 on the afternoon of Jan. 10th, 1885, in a delirious and unconscious condition. No history could be obtained from anyone until after his death, which took place on the following morning, the patient never having regained consciousness. His uncle then stated that on Thursday, Jan. 8th (two days before admission), the patient came home from school complaining of pain in his left knee, caused by a fall in the playground; he took to bed and began to shiver, this was attributed to "cold." On the Saturday he became unconscious; and the case being certified as "typhoid fever," he was removed to the infirmary. On admission the temperature was 105·2°; cardiac pulse 168. Patient delirious, very noisy, arms and legs stiff, constantly changing his position, legs drawn up, and muscles hard; slight herpes on lower lips; no mark of external injury, and no typhoid spots.

Examination of chest showed dulness at left apex in front with harsh breathing. Apex beat of heart absent and no radial pulsation. Continually moaning and occasionally crying out loudly. Ordered nepenthe draught, and after three doses he became considerably quieter. At 10 P.M. the left pupil was observed to be enlarged, the right contracted; later on they were both enlarged and acting sluggishly to light. At 1.15 A.M. on Jan. 11th the temperature was 103·6°, and at 7.15 A.M. (fifteen minutes before death) it reached 104·8°. From midnight until his death the patient was comparatively quiet, expiring suddenly at 7.30 A.M.

Necropsy (Jan. 12th).—Body well nourished. The only external mark was a small scar on the left knee; on the dorsum of the right foot there was a small abscess about the size of a pea, just under the skin. On opening the thorax, the lungs were observed to be deeply congested, especially the left at the apex. The heart showed numerous luxuriant vegetations on the mitral valve, and some other slight vegetations on the aortic valve. There was freshly deposited lymph on the front of the epicardium; and at the intermuscular septum there was an abscess under the epicardium, about the size of a pea. There was about half an ounce of fluid in the pericardial cavity; some clear fresh lymph was deposited over both pleuræ, but very sparingly distributed. Abdomen: No evidence of peritonitis. Right kidney weighed four ounces and a half; numerous abscesses were seen under the capsule, about the size of a pin-head, consisting of a yellow spot in the centre, with narrow area of congestion around. About half a dozen abscesses, the size of a pea, were seen extending inwards into the cortex about half an inch. The left kidney weighed four ounces; there were numerous pin-head abscesses here, the same as in the right, but no larger ones. Spleen large and congested, with three or four forming abscesses, a quarter to half an inch in diameter. Liver normal. Brain normal to appearance. Ventricles dry.

Remarks by Dr. SINCLAIR.—Any well marked case of this grave malady is always interesting and must be specially at the present moment, when we are all fresh from the perusal of the able Gulstonian Lectures of Dr. Osler of Philadelphia. It is matter for regret that this case was little more than twelve hours under observation, and that we were absolutely without any history until after the patient's death. It so happens, however, that he was seen shortly after admission, though at different times, by my friend Dr. Stalker and myself, and that we both expressed the opinion, quite independently of each other, that we should have pronounced the case as one of pyæmic infection had any cause been ascertainable. The cause, an injury to the knee, was obtained after death. It will be observed that here, as in most cases of malignant endocarditis, as Dr. Mitchell Bruce has well put it, "the phenomena of cardiac inflammation are comparatively subordinate to those of general infection."[1] It will be noted also that the patient was of an age at which the disease is comparatively rare. There were none of the antecedent sclerotic changes in the valves which have been so frequently observed. The lesions were of the vegetative and suppurative character, and, as is usually the case, were strictly limited to the left side of the heart. It is not difficult to understand the causation of the other pathological changes in the spleen and kidneys when the systemic circulation was being continually poisoned from the endocardial foci. I hesitate to express an opinion as to the possibility, or rather perhaps as to the probable frequency, of primary protopathic endocarditis, for which Dr. Osler pleads with great plausibility, because I have been so unfortunate as to have seen very little of malignant endocarditis. But I would venture to cast my opinion, whatever it may be worth, on the side of those who think the primary affection must be very rare. If in any case I could find no sufficient cause external to the heart, I would still hesitate to class it as primary, if I discovered any chronic valvular change, for the obvious reason that this of itself would form a starting-point which might, on very slight provocation, light up an acute destructive inflammation sufficient to inaugurate secondary pyæmic changes. Year by year, primary abscess of the brain—a somewhat analogous case in some respects—is becoming more rare, and is regarded by many as hardly existing, because careful inquiry usually discovers an antecedent disease or injury of the skull, most commonly of the temporal bone. In short, both ulcerative endocarditis and abscess of the brain usually owe their existence to some external cause, and the fault is usually ours if we fail to find it. Dr. Osler has, to some extent, lent the weight of his high authority to this view in his lectures. "Many of the cases occur after very slight injuries, as having a hangnail or corn; a sloughing pile; or the passage of a sound through a stricture."[2] Such a slight cause is only too apt to be overlooked. In the case above recorded, a comparatively trifling injury to the knee was sufficient to set up an attack which proved fatal in a very few days.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Serous Perimetritis.

A meeting of the above Society was held on Wednesday, June 3rd, Dr. J. B. Potter, F.R.C.P., President, in the chair.

The following specimens were shown:—By Dr. Gervis: Pessaries of Gelatine containing Glycerine and Boroglyceride. By Mr. Doran: A specimen showing Endometritis, Salpingitis, Oöphoritis, and Perimetritis, with Rupture of the Tube. By Mr. W. Griffith: A specimen of large Serous Perimetritis, producing complete intestinal obstruction, and evacuating itself by sloughing processes.

Dr. John Williams read a paper on Serous Perimetritis. An account of three well-marked cases was given, and a description of the appearances after death in one. Dr. Williams concluded that the disease was due to extension of inflammation from the uterus; that it commenced in the peritoneum in the neighbourhood of the ovaries, and extended along the brim of the pelvis, matting the intestines to the fundus of the uterus, and converting the pelvic cavity into a closed sac. Into this sac serum is effused, which raises the uterus upwards and forwards, and depresses the posterior wall of the vagina so as to protrude through the vulva in some cases. The effused serum becomes coagulated at the upper part, where adhesive peritonitis is present, and forms in some cases a considerable mass. This mass fixes the uterus and is the hard swelling felt after tapping.—Mr. Knowsley Thornton had seen two cases of the disease, one of which had recovered after tapping and drainage, and the other (presumed to be a similar case) had died without local treatment and without an autopsy. He urged that the connexion of the onset of these cases with delivery, abortion, and sudden checking of the menses points to escape of fluid from the Fallopian tube. The fluid, however, is not septic, as would be expected; indeed, if it becomes septic (as after tapping), the case almost always ends fatally in the absence of a free opening and washing out the cavity. The disease is practically a separate disease from ordinary pelvic peritonitis and cellulitis, with which all are familiar. The material causing serous perimetritis is evidently very irritating, as shown by the dense adhesions. He inquired whether the same solid material described by Dr. Williams was the result of irritation or of secretion under pressure. The pressure is indicated by the great pain accompanying the disease. As to treatment, aspiration is inferior to free opening by a trocar and maintenance of the opening so formed, with washing out of the cavity. Nothing answers so well for this purpose as a Cock's trocar and cannula, with a Wells' retaining spring for the cannula.—Dr. Gervis thought that cases of slight severity were not very uncommon. He differed from Dr. Williams in his explanation of the pushing of the uterus upwards and forwards, as also in hæmatocele. Dr. Williams thought this only occurred after the formation of adhesions, but Dr. Gervis had seen many cases in which this displacement occurred almost immediately after the effusion and before the fluid could have become encysted.—Mr. Doran agreed with Dr. Williams as to the usual route of the extension of the inflammation—namely, from the uterine cavity and along the tubes. In Dr. Matthews Duncan's book of "Parametritis and Perimetritis" a case is related in which the sound could be easily passed through the left tube into the peritoneal cavity. The rarity of serous perimetritis is probably due to the necessity of a combination of factors—namely, patency of the tubes, a particular sort of inflammation producing the effusion of serum, and the formation of a closed cavity by adhesions. Perimetric inflammation may be of parametric origin, by way of extension, but this is probably rarer than its origin as above described.—Dr. Graily Hewitt pointed out the analogy between effusion into Douglas's pouch (serous perimetritis) and effusion into the broad ligament (parametritis); the only difference being that of position. He thought the diagnosis of serous perimetritis from hæmatocele very difficult.—Dr. Godson believed serous perimetritis was not so rare as the author thought, and that its diagnosis from hæmatocele was often difficult. In Dr. Greenhalgh's time the ward at St. Bartholomew's had always several cases headed "Hæmatocele," and cases with the same characteristics were called by Dr. Matthews Duncan "perimetritis." As neither tapped these swellings, their pathology was so far doubtful.—Dr. Matthews Duncan esteemed highly this contribution to pathology, and especially the post-mortem in one of the cases. In Dr. Duncan's cases the fluid always ran off as in a perimetritic abscess, and he had no experience of the solid matter described by Dr. Williams. He had seen the serum set after it was drawn off, but he required full assurance as to its formation in the cavity containing the fluid.—Dr. Cleveland thought the use of the thermometer had not been sufficiently dwelt upon in the differential diagnosis between serous perimetritis and hæmatocele.—Mr. W. Griffith thought that the great difference of opinion among the speakers arose from the want of a precise definition of serous perimetritis. Some, who thought the disease rare, limited the term serous perimetritis to cases with large effusion. He believed serous perimetritis to be the commonest form of perimetritis by the analogy of pleurisy with effusion of serum and that of other inflammations of serous membranes, and by the displacement of the uterus and its rapid subsequent retreat. The specimen which he showed illustrated the occasional sudden disappearance of the signs, the serum escaping by rectum, vagina, and bladder, and not showing its presence as pus would.—Dr. Galabin had met with a fair number of cases in which encysted serous perimetritis had been diagnosed, and the diagnosis confirmed by the gradual disappearance of the swelling and the recovery of the patient. In one case, the resemblance to an ovarian cyst had been very close, a fluctuating swelling in Douglas' pouch being felt as a tumour reaching above the navel. A diagnosis of serous perimetritis was made because of the acute inflammatory symptoms with which the affection began. It eventually disappeared completely. He had only once tapped a serous perimetritis, and that in consequence of an error in diagnosis. Tapping was generally inadvisable. His case illustrated the fact that these cases may sometimes have the rigors and high temperature usually thought to indicate pus. It was aspirated, and clear serum drawn off with antiseptic precautions. The patient became worse, showing septic symptoms, the swelling filled again; a free incision was made, a large drainage-tube kept in, and the cavity washed out with a weak solution of iodine. The patient recovered after a serious illness.—Dr. CHAMPNEYS had noticed the flakes of lymph described by Dr. Williams in fluid recently drawn from a case of serous perimetritis under his care. He had lately had a case in St. George's Hospital in which a pouch of clear serum existed side by side with an ordinary pelvic abscess. As regards the surgical treatment, it must be remembered that the walls of the cyst are dense and unyielding, and would not readily collapse; in this lay one of the dangers. If such a collection were opened, antiseptic treatment should consist of careful antiseptic cleansing of the vagina and of the instruments; and in addition, he believed that it was well to leave an iodoform pessary, which would melt slowly, in the vagina, as a precaution against any germs which might attempt to gain an entrance. He believed that a differential diagnosis without tapping was impossible more often than not. He would remind Mr. Griffith that a very small enlargement of a pelvic organ—such as an ovary—is sufficient to displace the floating uterus, and that displacement was not an absolute evidence of effusion.—Dr. WILLIAMS, in reply, said that his first case was improved by tapping; that she died from severe diarrhœa, for which there was ample cause other than sepsis, and the contents of the sac were quite sweet and antiseptic after death. The little serum at the bottom of the sac was clear and sweet. As to the rarity of the disease, Dr. Williams was surprised to hear from several speakers that they had seen several such cases. There were only about half a dozen cases on record, and the majority of the systematic writers on the diseases of women said little or nothing about it. The three cases recorded in the paper were the only three that Dr. Williams had seen and recognised. Mr. Doran's ingenious explanation of the extension of inflammation along the Fallopian tube to the peritoneum in some cases and not in others was deserving of attention and study. Dr. Williams thought it probably a correct account of what took place. Dr. Matthews Duncan asked if the solid serum was the result of post-mortem change. Dr. Williams thought it was not, because the solid mass was discovered by Dr. Hewitt and himself during life above the layer of fluid in the most dependent part of the sac, flakes of it were passed in the second case; and in the three cases a similar hard mass was discovered at the top of the sac during life, and Dr. Matthews Duncan had found the same physical signs after tapping signs which the presence of the coagulated fluid fully explain.

---

[1] Quain's Dictionary of Medicine, p. [illegible].

[2] Lecture II.

Mr. WALTER GRIFFITH showed a specimen of Pseudo-osteomalacic Pelvis of Naegele. It was bought in Paris by Professor Humphry of Cambridge, and lent by him. It was obviously rachitic, but had some of the characteristic deformities of mollities, including a much-curved, instead of a flat sacrum, much-curved iliac fossæ, and a triangular in place of the usual flat brim; the posterior part of the ilia was moulded round the sacrum. The pubis, however, was not beaked, as was the case in other specimens of this type. It was suggested that the cause of this unusual deformity was a severe form of rickets occurring later in childhood than usual. References were given to other recorded specimens, and to papers on the subject by Smellie, Dr. John [illegible] of Glasgow, Naegele, Michaelis, Litzmann, and [illegible]. Photographs and detailed measurements were also given.—Dr. CHAMPNEYS regretted that the author had not adopted the plan which he had himself followed when he had brought abstruse pelves before the Society—viz., that of having the specimen on view with the paper at the library for the study of Fellows. Speaking from a cursory view of the pelvis, he thought the disease appeared to have attacked the pelvis unequally, the posterior parts being much more deformed, and bearing much plainer evidences of softening, than the anterior parts. The specimen was of great interest.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Surgical Section, on March 20th,

Mr. WHEELER read a paper on Complete Excision of the Clavicle for Osteo-sarcoma, and on Partial Excision of the Clavicle for Necrosis. Both patients recovered, and he had seen the first nine years after the operation; he was in good health, and had admirable use of his arm.—The PRESIDENT suggested that the paper should have been entitled "Excision of Diseased Clavicle," instead of "Excision of the Clavicle." Excision of the healthy clavicle was of easy performance; but that of a diseased clavicle was an operation of great difficulty, according to the disease affecting it. The power preserved in the upper extremity was wonderful, as though the patient had some power of supplementing the want of the bone.—Mr. TUFNELL, having had the opportunity of witnessing both operations, called attention to the advantage of previous examination of the chest and kidneys. In the case of the man on whom Mr. Wheeler had operated, both were found sound, and but for the examination the operation would not have been performed.—Mr. WHEELER, in reply, said the reason he did not actually entitle his paper "Excision of Diseased Clavicle" was that at the outset he stated it to be a case of osteo-sarcoma.

Mr. WHEELER also read a paper on Excision of the Shoulder.—Mr. THORNLEY STOKER recognised the result of Mr. Wheeler's skill in the example exhibited to be almost beyond criticism. But he challenged Mr. Wheeler's statement that it was necessary to fall back upon military statistics for a knowledge of the success attained in dealing with gunshot injuries. There was no parallel in the conditions of operating for gunshot injuries in the field and operating in civil practice for disease, the circumstances and surroundings being entirely different, and also the fact of the well-known mortality attending operations in the field.—Mr. BARTON concurred with the author that the operation of excision of the shoulder was rare, but in the reasons for it the most important one was omitted—namely, that the shoulder-joint was subsidiary to the movements of the scapula on the ribs. The condition of an ankylosed shoulder was very different from that of an ankylosed elbow, which rendered the upper extremity useless, and therefore a recognised operation which every surgeon would perform. But an ankylosed shoulder-joint was by no means useless. The supplemental movement of the scapula on the ribs gave such a wide range of motion that it became unnecessary to operate. For his own part, instead of a straight incision through the deltoid muscle he preferred a **U**-shaped incision posteriorly, about the middle of the scapula, and taking in the posterior edge of the deltoid, as giving ready access to the joint, and natural drainage. He was not obliged to do more than scrape off the diseased cartilage from the glenoid cavity. Mr. WHEELER, in reply, said Mr. Stoker had missed his remark that for comprehensive statistics they had to go to military surgery, because in civil practice the operation was comparatively rare. As to the well-known mortality in the field, the statement was open to exception, because in Larrey's cases all the first succeeded, whereas in the Schleswig-Holstein campaign there appeared to have been great mortality following amputations of the shoulders and legs; and, again, in the next serious battle cases of excision of the shoulder did very well. It was therefore unaccountable why there was great mortality consequent on operations on some fields of battle and very little on others.

Mr. SWAN read a paper on Condylotomy by the Osteotome for the Treatment of Knock-knee. He had practised Mr. Reeves' operation exclusively, but he had found it futile to avoid entering the joint. During the past four years he had operated on sixty-eight individuals, and [illegible] knees in all were operated upon. The ages ranged from nineteen to three years and a half. Nineteen had both knees operated on simultaneously. Suppuration occurred only twice, and all the cases recovered with useful limbs. Mr [illegible] had witnessed a good many of the operations, and considered the Section indebted to Mr. Swan for his [illegible] and its successful character. Like the peritoneum, the [illegible] of the knee-joint had during his time undergone a revolution. The simplicity of the operation, as done by Mr. Swan, was marvellous, and the results had been most satisfactory. It was a source of pride that Dublin was not behindhand in the great advance made by orthopædic surgery within the past few years.—Mr. Thomson congratulated Mr. Swan on his valuable contribution to orthopædic surgery. Having seen several of the cases, he could testify to the skill with which the operation had been done, and to its apparent simplicity.—Dr. R. M'Donnell also congratulated Mr. Swan, many of whose cases he, too, had seen. The results were amazing, and such as a few years ago none could have believed. He had himself learned a severe lesson, having lost a patient from the simple operation of aspirating, though it was done with the greatest care, and with an instrument which had never been used before. The result of that case, which he published as a warning to others, made him timid in meddling with knee-joints.—Mr. Barton concurred as to the value of the communication in proving that the surgery of the deformity in question was on a basis of security. But it would be a mistake to conclude that, because Mr. Swan was able to bring forward so many cases with such a happy result, therefore Reeves' method was *par excellence* the best. He regarded Macewen's as superior to it, although he had not tried Reeves'. The results of Macewen's operation in fourteen or fifteen cases in which he had operated were exceedingly successful, as showing that it was free from danger, that recovery was rapid, and the condition of the limbs thoroughly satisfactory. Therefore, supposing Mr. Swan's sixty-eight cases to have resulted in perfectly straight limbs, if Macewen's method could turn out limbs quite as good it ought to be preferred, since the joint was not opened. Indeed, with proper precautions Macewen's operation might be performed on both knees at the same time without risk of rise in temperature, or of suppuration.—Mr. Wheeler considered it impossible to perform Reeves' operation without opening the joint.—The President pointed out that the operation performed by Dr. R. M'Donnell was for a joint already diseased, whereas Mr. Swan's operations were all in the case of healthy joints.—Mr. Swan replied. Without expressing an opinion in favour of either operation, he was disposed to think that the freedom of the incision, the patulous condition of the osseous opening, and the easy escape of fluid, conduced to the immunity from risk. He used the spray as a concession to prejudice, but he had not used it in the last twenty or thirty cases. At the same time, he followed antiseptic surgery, and always dressed a case under the spray, thereby feeling confidence, and the method being useful in moistening the dressings.

Reviews and Notices of Books.

A Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. Lauder Brunton, M.D., D.Sc., F.R.S., Lecturer on Materia Medica at St. Bartholomew's Hospital, &c. &c. Adapted to the United States Pharmacopœia by Francis H. Williams, M.D. Boston. London: Macmillan and Co. 1885.

In a recent article in The Lancet we pointed out that to the term pharmacology is no longer assigned the old significance which it bore as a synonym of materia medica. It is the science of the action of remedies, and deals with the modifications produced in healthy conditions by the operation of substances capable of producing modifications. It is essentially a branch of physiology, and is equivalent to the phrase "the physiological action of drugs." It constitutes, as has been very justly remarked, the chief basis for the application of remedies in disease, and is the connecting link between materia medica on the one hand and the art of medicine on the other. That it has hitherto been but imperfectly taught in our medical schools is generally admitted, and the explanation usually given is that it is impossible to teach it well because there is no trustworthy text-book on the subject in the English language. The appearance of Dr. Lauder Brunton's comprehensive work will save us from this reproach in the future. That its publication has been so long delayed is a subject for regret, but it is so complete, even to the minutest detail, that we cannot help feeling that we have not waited in vain.

The work opens with a chapter on the relations between the organism and substances by which it is affected, a subject which is dealt with in a manner possible only to one who is both a chemist and a physiologist. The second chapter, treating of circumstances affecting the action of drugs on the organism, is a masterly essay deserving careful study and consideration. From the outset it is seen that the work has little in common with the old-fashioned books on materia medica. It is not a mere collection of dry facts and technical details, but a scientific treatise worthy to be ranked with the highest productions in physiology, either in our own or any other language. The information is conveyed in a form in which it will be readily assimilated even by a first year's student. The author commences with the simplest facts, and gradually step by step leads up to the latest development of science. Everything is practical, the dry, hard facts of physiology being pressed into service, and applied to the treatment of the commonest complaints. It is a book of study for the scientist, and a work of reference for the practical physician. The information is so systematically arranged that it is available for immediate use. The index, which is divided into three parts, occupies considerably over a hundred pages, and is so carefully compiled that a reference to any special point is at once obtainable. The arrangement of the type is novel, and enables the reader to see almost at a glance in what cases, or under what circumstances; the use of any particular remedy is indicated. Dr. Brunton is never satisfied with vague generalities, but gives clear and precise directions for prescribing the various drugs and preparations which he recommends. Much of the work is the result of his own observation and mature experience; but where he has had to rely on the statements of others, he has been most careful to assign to them their full share of credit. The references to foreign literature are wonderfully complete, and will be of great assistance to original workers. There can be no doubt that the publication of this text-book will have an important influence in improving the status of pharmacology in this country. That materia medica as an educational agent is a thing of the past is certain, and it is equally certain that its place will be taken by a systematic study of pharmacology. The whole subject has of late years been undergoing a gradual but slowly progressive change. We congratulate Dr. Lauder Brunton on the appearance of his masterly work, which will ever remain a monument to his genius and industry, and we congratulate students on being at last placed in possession of a scientific treatise on a subject of enormous practical importance.

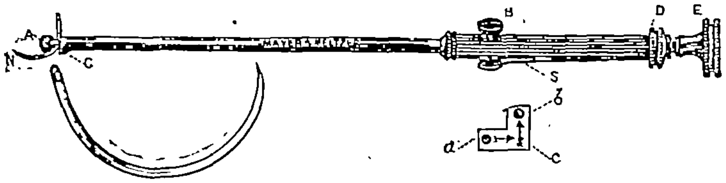
Elementary Text-book of Zoology: Special Part, Mollusca to Man. By Dr. C. Claus, Professor of Zoology in Vienna and Director of the Zoological Station at Trieste. Translated and Edited by Adam Sedgwick, M.A., and F. G. Heathcote, B.A. With 706 Woodcuts. London: W. Swan Sonnenschein and Co. 1885.

The second volume of Mr. Sedgwick's translation of Claus' Elementary Text-book of Zoology has appeared very speedily after the first. It includes the Mollusca, Molluscoidea, the Tunicata, and Vertebrata. Though essentially a treatise on Zoology, the present work differs in an important respect from the older books on the same subject in giving not only the differential characters of the various families with their distribution, but a good, though short, account of their internal organisation. Thus, to give one example: in the Cephalopoda, which are defined as Molluscs, with well-defined head, "a circle of arms bearing suckers round the mouth, and funnel-shaped, perforated foot, diœcious," the chief forms are lightly sketched, and a description given of the funnel, the chromatophores, the cartilaginous skeleton, alimentary canal, nervous system, sense organs, respiratory and circulatory systems, the sexual glands, and finally of the development of the group. This section alone is illustrated by sixteen well-executed woodcuts. In the account of the other groups also illustrations abound of typical examples. With this work, a good museum at hand, and a set of dissecting instruments, the student might obtain a very fair and full knowledge of the animal kingdom, such knowledge as would prove serviceable to every medical student, and would give him such general information as would render the study of human anatomy extremely interesting. We must congratulate Mr. Sedgwick on having executed an excellent translation of a very useful book, and Messrs. Sonnenschein on the admirable manner in which it is got up, the type, and especially the woodcuts, being extremely clear and good.

New Inventions.

A NEW NEEDLEHOLDER FOR VAGINAL OPERATIONS.

THE needleholder shown in the accompanying sketch, though not apparently much like Hagedorn's, is really a modification of that valuable instrument. It was designed for using with Hagedorn's needles, and with the view of obviating certain inconveniences which had been noticed in using his holder. These defects were remarked upon some time back by Mr. J. W. Hulke, when, in the course of an operation for a vesico-vaginal fistula, in which it was necessary to reach the posterior fornix, he used Hagedorn's holder for putting in the sutures. The two principal objections which he raised to that instrument were the following:



A and C are copper-faced pieces, between which the neeedle is grasped, A being pressed against C by a clamping screw (inside the shaft of the instrument) worked by the large milled head, E. D is another milled head fixed on the handle for the purpose of giving a firm grip when clamping a needle in with E. D is the pressure knob (there are two of them) for releasing the needle. It works in a rectangular slot in the handle shown on a larger scale below in the diagram. When the instrument is ready for use, with a needle clamped into it, D is in the position *b*. To release the needle, B is moved by the thumb from *b* to *c*, and it is then shot from *c* to *a* by a spiral spring inside the handle. To replace the needle for another stitch, E is slackened half a revolution, and then pulled on. By this means B is moved from *a* to *c*, and then shot from *c* to *b* by the small spring, *s*, when the needle can be replaced between A and C, and clamped there by means of the milled head, E. N is a needle clamped in the instrument, and ready for use.

(*a*) The forceps handles of Hagedorn's instrument make the hand occupy so much space that it cuts off the view into the vagina, and cause inconvenience in other ways where the space is so limited as it is about the vulva. (*b*) When a considerable thickness of uterine tissue has to be included in a suture, the needle sometimes slips, the grip of this holder upon the needle being scarcely firm enough to hold against such resistance as is then encountered. In addition to these defects it was found that when Hagedorn's holder is held in some positions, it is difficult to get at the releasing apparatus without changing the position of the grip of the hand upon the instrument to a considerable extent, and in so doing running the risk of displacing the needle from the tissues into which it has penetrated. The instrument which is here shown meets these objections in the following manner. Regarding (*a*), the difficulty is overcome by doing away with the forceps-like form of the instrument, and by having instead a round handle about three-quarters of an inch thick. Regarding (*b*), the grip of the instrument upon the needle can be almost indefinitely increased, as the needle is grasped by means of a clamping screw. This screw is cut with a very fine thread, and being worked with a large milled head, can be made to take an exceeding firm hold. To obviate the remaining defect, in the new instrument the needle is released by a trigger-like action, the release being effected by pressing against a button with the thumb. There are two of these buttons on this instrument, and they are so placed that in whatever position the instrument might happen to be grasped, one of them would be presenting to the tip of the operator's thumb. The instrument has been made by Messrs. Meyer and Meltzer of Great Portland-street, and I am much indebted to them for the skill with which they have carried out my designs. The instrument has been used by Mr. Hulke for a case which presented about as much difficulty in reaching the fistula and putting in the sutures as would be likely ever to occur. He said after the operation that the instrument was the most efficient he had ever yet used for the purpose.

Appended hereto is a sketch of the instrument, and a short description of its working parts and the method of using it.

ARTHUR E. NEVINS,
Middlesex Hospital. One of Mr. Hulke's late Dressers.

PATENT POSTAGE STAMP AFFIXER.

WE have had submitted to our notice a machine for affixing postage stamps which has been invented and patented by Mdlle. Victoria De Bunsen. By its use the injurious habit of wetting with the tongue the stamps and flap of the envelope is obviated, and as it is stated that 100 stamps can be affixed in five minutes by an experienced person with this machine, it is apparent that by its use a vast waste of time will be avoided by those who are in the habit of using stamps in any considerable number. Not the least merit of the apparatus is its simplicity and the absence of complicated movements in its employment. It is exhibited in the International Inventions Exhibition, where it may be inspected by those interested in such an appliance.

HOLLOW EYE SPECULUM.

To the Editor of THE LANCET.

SIR,—In a description of a hollow eye speculum (THE LANCET, June 20th, p. 1130) Mr. E. Treacher Collins does me the kindness to refer to my lid-irrigator described by me at the meeting of the British Medical Association at Belfast last year. As an illustration of parallelism in ideas, allow me to say that the first idea of my contrivance was a douche passed through the two limbs of a speculum. But a modification was made into the present lid-irrigator because (1) in severe cases, where there is much intumescence of the lids, the irrigator can be easily introduced where a speculum is difficult of application; (2) the stream can, with the irrigator, be readily directed to the angles of the conjunctival cul-de-sac; and (3) during the whole of the manipulations the upper lid can be held away from the cornea. The whole object aimed at is a lengthened and complete application to the upper cul-de-sac. There is no difficulty in treating the lower lid; the lower limb of the douche was found to be superfluous and to interfere with the movements of the upper jet. As a practical man, I should advise nobody to trust any instrument to the patient. If you wish cases of gonorrheal ophthalmia to be saved, see them yourself, and see them often. Mr. Collins, in modifying my instrument, has gone back to an earlier stage of its evolution, and I am constrained to say that I think my own simplified form is the better instrument for practical work.

I am, Sir, yours, &c.,

EDGAR A. BROWNE,
Senior Surgeon, Liverpool Eye and Ear Infirmary.
Liverpool, June, 1885.

THE LANCET.

LONDON: SATURDAY, JUNE 27, 1885.

Though personal, social, and scholastic prejudices and predilections may never be entirely eliminated from the election of members of the Council of the Royal College of Surgeons, it is certain that they have not now the preponderance they once had. The political education of the electors is advancing—slowly, it is true, but surely; and the time cannot be far distant when the elections will be determined rather by political considerations than by personal sentiment or caprice. It will soon, we trust, cease to be regarded as a qualification for a seat in the Council that a candidate belongs to this or that hospital and medical school. The Council should represent the interests of the surgical profession, and especially those interests which more particularly affect the status and professional well-being of the Fellows and Members of the College. The only influence that the so-called representation of the schools ought to have upon the result of any election should be to prevent any school from being over-represented. The representation of particular schools has indeed been a glaring defect in most of the College elections; for although the Charter does not explicitly suggest such representation, it does so implicitly by requiring exclusive personal voting. By this provision the election of members of Council has been thrown into the hands of those Fellows who reside in or near London, and who are therefore more liable to be affected by the influence of the schools than those who reside in the provinces. When Fellows are allowed to vote either in person or by papers, it may be expected that not only will the constituency be enlarged, but its independence and intelligence will be proportionately increased. Meanwhile the election must take place on the old register, and to some extent on the old lines.

The questions before the electors are extremely simple. The Council is full of anomalies and abuses. Not only does the Council elect the examiners, but every member of the Council is himself eligible to be elected as an examiner. Until a few months ago every member of the Court of Examiners and one member of the Board of Examiners were also members of the Council; or, in other words, eleven of the twenty-four members of the executive annually appropriated an aggregate of £5000 from the revenues of the College. Again, the office of President has hitherto been conferred on the senior member of the Council in rotation, whatever his degree of fitness or unfitness. And lastly, the Council has always exercised the privilege, and still deliberately claims the right, to make whatever alterations it pleases in the constitution and relations of the College, without consulting the opinions or wishes of the Fellows and Members whom it nominally represents. Endeavours have been made to remedy these evils, but a majority of the members of the Council has repeatedly resisted every attempt, whether originating from within or without the Council. Of the candidates for election next Thursday, Mr. Savory, the retiring member of the Council, is known to have sided with the opponents to change; while two—namely, Messrs. F. Mason and Rouse—have not as yet publicly expressed an opinion for or against. On the other hand, Messrs. Gant, Cowell, Macnamara, and Pemberton have identified themselves with the policy of a thorough and comprehensive reform of the Council.

Whatever be the result of the election next Thursday, it is to be hoped that those who do vote will not stultify themselves by resorting to the absurd system of plumping. Three members of the Council are to be elected, and those who have not the courage or capacity to give *three* votes, should at least preserve the semblance of intelligence so far as to abstain from voting at all.

◆

The curiosity which has so long prevailed as to the line of reform in the constitution of the University of London to be submitted to Lord Justice Fry's Special Committee by its sub-committee will be satisfied this afternoon (Friday). The draft scheme recommends changes sufficiently radical to satisfy the most advanced reformer, and, if adopted by the Special Committee, will demand the gravest consideration by Convocation and the Senate. The scheme is so thorough and so practical that we can hardly believe it can be rejected by either of those bodies. By it the entire constitution of the University will be remodelled. Instead of being composed of two bodies only—viz., Convocation and the Senate—it is proposed that it shall consist of constituent Colleges, Faculties, and Boards of Studies in addition, and that the mode of election to the Senate and the period of senatorship be completely altered. The Senate will consist of thirty members, with a Chancellor, Vice-Chancellor, and the Chairman of Convocation, as at present; but the Crown nominees and the direct representatives of Convocation will be limited to six each, whilst each of the four Faculties of Arts, Science, Laws, and Medicine are to elect three, and the constituent Colleges six. The constituent Colleges named are—University College, King's College, the Royal Colleges of Physicians and Surgeons, the Council of Legal Education, and the Incorporated Law Society. Moreover, whilst the collegiate representatives may serve for three years, one-third of each of the other groups are to retire yearly, so that in this way an infusion of new blood may be steadily secured. The advantages of such a Senate over the present fixed body are self-evident, and must commend the scheme to all well-wishers of the University. Lest the existing members should consider the proposed change an infringement of their special privileges, the Faculty and College members are to be added to the present Senate, and no new members are to be appointed by the Crown or by Convocation until their representatives respectively fall below six. This is a very judicious method for securing the needed changes with the least disturbance of the existing arrangements. Convocation remains unchanged. The constituent Colleges are to be named partly by a joint committee of the Senate and Convocation and partly by the Senate, with the concurrence of the Faculty or Faculties interested. In this way it is hoped that a closer bond may be introduced between the Colleges and the University. The most important alterations, however, will be in the formation of Faculties and Boards of Studies in each Faculty. The Faculty will give instruction to the Board of Studies, and this will in turn advise the Senate on all examinations and changes in regulations, and without such advice the Senate is not to act. As the Board of Studies will be composed almost entirely of teachers and examiners, the Senate will have a skilled body to appeal to for advice in any difficulty. At present an attempt is made to please everybody—teacher, student, and examiner—and of course neither is satisfied. Lord Justice Fry must be congratulated on the thorough manner in which he has gone to the root of the difficulty, and on the practical scheme he has devised for its solution.

UNTIL recently the treatment of palmar ganglion had been a reproach to surgery. The nature of the affection has been understood, and its ill effects upon the function of the hand have been well recognised, but in most cases only slight and unavailing measures for its relief have been taken, because the more radical modes of treatment have been fraught with much danger to life and limb. Treatment by pressure, by the application of counter-irritants, or even by tapping, has been almost universally unsuccessful, and injection of irritant solutions and incision of the synovial sac have been followed by failure, adhesion of the tendons, or even by death. Injection has failed probably from the presence of the "melon-seed bodies" so often found in these cysts. Whenever suppuration has been excited in the tumours, there has been great danger of blood poisoning in some form, and if this danger have been escaped, the tendons projecting into the sac have been firmly fixed as the cavity filled up, and a more or less useless hand has been the result. Our modern improved treatment of wounds has enabled surgeons to grapple successfully with these difficulties, and it is now possible to lay down definite rules for the treatment of palmar ganglion, and of similar synovial cysts in other situations. The first point of importance is to attempt the cure of the cases as early as possible. No good can come of delay, which merely leads to greater distension of the cyst, and is especially to be deprecated as endangering the adjacent tendons, which become stretched and even in some cases severed, by the pressure to which they are subjected. As soon, then, as the disease is clearly recognised, treatment should be undertaken. The second point is that any treatment to be successful must consist in the free evacuation of the cyst and the removal of all the "melon-seed bodies" it contains, whether these be free in its interior or adherent to its walls. For this purpose an incision about an inch and a half long, not a puncture, should be made in the most prominent part of the swelling, above the annular ligament, avoiding, of course, the radial vessels and the tendons, which can be felt through the skin. Pressure should be made in the palm to force out the fluid and as many of the loose bodies as will thus escape. Then a sharp spoon should be introduced, and the whole cavity scraped, to detach any "bodies" which may be still fixed to the synovial membrane. The "spoon" is much the best means of doing this. Some have trusted to injecting a full stream of fluid into the cyst, but this will not remove "bodies" which are still firmly adherent to the cyst wall. Volkmann passes a large drainage-tube through the cyst, and draws it sharply to and fro, and trusts to that to detach any adherent "bodies"; this is, however, an uncertain method, and if the cyst be old and large, with pouches extending from the main cavity, they escape the friction of the tube altogether. Having thus carefully removed all the contents of the cyst, whether solid or fluid, a solution of chloride of zinc, forty grains to the ounce, should be applied to the whole interior of the sac, the purpose of this being so to modify the nutrition of its lining as to prevent any recurrence of the dropsy. A solution of iodine has been used for the same purpose, and some surgeons may be inclined to use iodoform instead. The most important steps in the treatment are those to be taken to secure healing of the wound without suppuration—at any rate, without septic suppuration. As a preparatory step the parts must be thoroughly cleansed before the incision is made, and the operation should be conducted under an antiseptic spray or irrigation, and some efficient antiseptic dressing should be finally applied. Guérin's cotton-wool dressing has been used with success, so has iodoform wool; and, of course, the Listerian carbolic gauze dressing. A drainage-tube should be introduced into the wound and passed down beneath the anterior annular ligament, and only removed when the discharge through it is reduced to a minimum. The question of drainage has been much discussed. Some surgeons have contended that a second opening should be made into the cyst in the hand, and a tube be laid quite through from one end to the other, or two tubes used, one in each wound. Others have advocated several smaller incisions, or even one incision extending along the whole length of the ganglion. All these seem to be unnecessary, and Dr. Weiss has recently published in the *Revue de Chirurgie* two cases illustrating this fact, and in his excellent remarks appended to them he has argued out this point. He shows that if pressure be carefully applied over the palmar part of the cyst, all retention of fluid can be entirely obviated. The hand should be kept fixed on some kind of splint applied to the extensor aspect, until the wound inflicted is healed. As soon as that is accomplished, the fingers should be liberated and the patient be encouraged to move them. The results of this treatment are totally different from those formerly met with. When the antiseptic precautions are successfully carried ont, there is no danger whatever of blood poisoning or of profuse local suppuration, and the final result is the restoration of a thoroughly useful hand. The tendons are not bound down by cicatricial bands, and after a time it may be impossible to find any trace of the previous mischief beyond a linear scar in the forearm. In this way, therefore, surgery is now able to offer to these patients a thorough cure of their malady, and without serious risk, while formerly the cure was imperfect, and was attended with considerable danger.

An interesting question still awaits an answer. How is the cure of the synovial cyst accomplished? Is it by granulation, or direct adhesion of its surfaces? If so, why are there no adhesions to bind down the tendons and impede the free use of the fingers? Is the process of cure analogous to that obtained in a hydrocele by injection, or in dropsy of a joint treated by injection of iodine? This is the view held by Weiss and others. If so, it remains to be shown why the cases do not relapse, as so often occurs in hydrocele. At present no case of recurrence of the ganglion after aseptic incision and drainage has been reported. Until post-mortem observations are available in cases which have been cured by this operation, it will be impossible to speak with any assurance upon this point. Meanwhile the success to be obtained, if only care be taken to observe all the necessary conditions, is so great that this operation may be practised with confidence, even although we may have to wait before knowing the exact pathological changes that take place.

◆

If there should be present to the consciousness of any one of our readers a sense of longing for greater intellectual activity than the calls of professional duty necessitate, we would commend to his consideration the study of the "Revised Instructions to Her Majesty's Inspectors of Schools." For ourselves, we must confess to being mentally prostrated by the endeavour to read the riddle of this mysterious paper aright. The general impression left on our mind is that Her Majesty's inspectors of schools must be a class of raging lunatics if only one-half of the "instructions" issued for their guidance are requisite. For example, they are expressly cautioned against trying to do two things at once, such as giving out dictation or sums while hearing the reading of another class. They are not to show their temper, &c. &c. In short, the suspicion of their mental soundness is irresistibly suggested by the remarkable general resemblance which these "Instructions" bear to those which the medical officers of well-conducted lunatic asylums are wont to issue for the benefit of patients discharged on probation or let out on leave. Nothing more calculated to make the public conscience uneasy as to the mind-misery inflicted on young children by the way in which the Education Act is carried out than these "instructions" can well be conceived. In one, and so far as we can see only one, respect have matters been mended by the recent agitation with regard to over-pressure. The responsibility will henceforth rest with school managers and teachers of the undue taxing of the powers of weakly children. The inspector is, however, still let loose on the school, in this respect in a manner his implied state of mind scarcely justifies, for he may insist on seeing the children who may be kept back because they are deemed "of feeble or slow intellect," and unless he—the man whom it is necessary to warn against himself trying to do two things at once, and being hurried and showing undue haste—is satisfied, the precaution of managers and teachers is to go for nothing. Surely this is a very perilous state of matters. It is not asking too much to demand that a *medical* examination should be made, and that the certificate of a qualified practitioner should suffice to reduce the inspector to order. No educational system can ever, we are convinced, be safely worked until it comes to be recognised that not the glorified pedagogue who now figures as "inspector," but a medical practitioner, is made the judge of physico-mental fitness to undergo, and survive, the brain-torturing process which the most enlightened Legislature of modern times has mistaken for education. We are so thankful for small mercies that it would be absolutely unjust to acknowledge that the poor little half-starved gutter child, whose knowledge of the science of music has hitherto been derived from an outside study of the peripatetic hurdy-gurdy, and whose acquaintance with the quality of musical time has been picked up while dancing with bare feet to the music ministered by the itinerant organ-grinder, is to be henceforth graciously excused from "naming the value of the notes rhythmically and in time without *singing them*." It will now suffice to sing them. If any father of a family desires to form a just estimate of the magnitude of the task remitted, let him call upon one of his own highly educated children, upon whose culture much money and time have been bestowed, and who is *supposed* to have "a taste for music," and ask Master or Miss Hopeful to give him a specimen of the exercise from which the poor little waif is at length excused.

Annotations.

"Ne quid nimis."

WELLINGTON COLLEGE AND RUGBY SPEECH DAYS.

The annual gala day at Wellington College and at Rugby took place on Friday and Saturday of the past week. As is usual, the head-master of each school, Dr. Jex Blake of Rugby and Mr. Wickham of Wellington, made their respective addresses to the parents of their pupils, who on such occasions assemble in considerable numbers to witness the distribution of prizes and listen to the speeches of the boys and yearly statement of the head-master. These are not without interest to members of the medical profession. The two accounts are in curious contrast with each other. While at Rugby the head-master could congratulate the boys on their achievements both at the Universities and in the cricket field, the head-master of Wellington made apology for the paucity of honours gained by the boys at his school, small enough in the past compared with some other public schools, but smaller still in the present year. One advantage Wellington appears to offer is being able to send pupils straight to Woolwich without the intervention and aid of the system of private cramming, which of late years has grown so prevalent an adjunct to public school education. In this respect it competes with Cheltenham College. These two schools draw their students from very much the same spheres, possibly Wellington somewhat more from the *élite* of society and the army; but these should not be either intellectually or physically below the standard of the other school. What is it then which gives to Rugby the pre-eminence? The scholarship of the staff of masters is very much on a par at both schools. Boys destined largely for the army, as those at Wellington are, should not be inferior to those intended for civil callings in life either in intellectual culture or prowess in games. They should be in association with boys capable of successful competition at the universities to catch their spirit of culture if they cannot equal them. Yet, on the showing of the two head-masters, there appears to be a wide difference in this respect at the two schools. Wellington boys are behind Rugby boys in competition at the universities. Has the difference in locality anything to do with this? Rugby is situated on a high table-land where the wind blows with an invigorating force and braces to the fullest energy, while Wellington College is on a low-lying plain with adjacent hills which drain into the marshes below, rendering the air damp and enervating. In this country, and probably elsewhere, those who dwell on higher lands are less liable to disease than the dwellers on plains, especially marshy plains, and anything that predisposes to disease enervates the system and lessens the capacity for mental and physical energy. While the head-master of

Rugby could congratulate his school on having a system which enabled them to stamp out infectious illness, the head-master of Wellington had to acknowledge, in terms of affectionate remembrance, the sad death of the late bursar of the College, who succumbed to an attack of septicæmia in November last, making one of a series of deaths from this disease which had been fatal to several of the pupils in previous years. The head master of Wellington referred also to the early death of one of the former pupils of the College just as he had secured admission to the Engineers. It would be interesting to learn the proportion of deaths at all our public schools, among the pupils actually there and within ten years of leaving, to enable the primary cause of death in early manhood to be traced back, and we have good reason to believe this could often be referred to school life, little as parents suspect it.

CONVEYANCE OF SCARLET FEVER BY A THIRD PERSON.

THE *Medical Record* of New York contains the report of instances of this sort. It would be very remarkable if anything but communication of the disease had occurred. A lady stayed with her sister, who had five children ill with scarlet fever. She went home, twenty miles distant, and a daughter and a niece took the disease in five days. The niece died. There had been no scarlet fever in the neighbourhood for months. In the other cases doctors, of whom wiser things might have been expected, were at fault. One was the doctor in the above fatal case. He took the dying child in his arms, where she actually did die. In four days his boy took the disease, and in another four days a second boy. We should not omit to say that he allowed the first boy to climb into his lap and remain there an hour after returning from the final scene and service above referred to. Since this experience the medical man has always worn rubber clothing in the sick room of a scarlet fever patient. In another case the medical man held a little scarlet fever patient on his knee while he made an application to the throat. On his return home his son climbed up into his lap before he had time to remove his overcoat. Soon afterwards he took the disease, and other children followed. Surely, there is nothing astonishing in such facts but the utter obviousness of them. If the transmission of the disease had been intended, the devices could not have been more perfect. In this country many adopt the precautions of a long surplice for the sick room and washing of the hands, which are quite effective.

SCHEME FOR A MEDICAL SCHOOL IN DUNDEE.

EVER since University College, Dundee, was fairly equipped for its work, the hope has often been expressed in many quarters that a medical school would in time be attached to it; and since the appointment of Mr. D'Arcy Thompson, a distinguished graduate of Cambridge, to the chair of Biology last winter, the hope has taken more definite form. Mr. Thompson has already done excellent teaching and original work in Dundee on the lines adopted by the Cambridge school which recognises Dr. Michael Foster and the late Prof. F. M. Balfour as its two chief apostles. The professorial staff in Dundee are convinced that a medical school would give to the college more definite aims than it can aspire to at present. A town of the size of Dundee, with its 150,000 inhabitants and its splendidly-equipped infirmary, would in Germany hardly remain long without a medical school. The infirmary has 250 beds, an average of 150 in-patients, and a large out-patient department. The clinical material is ample and varied, and is drawn not only from the town and neighbourhood, but also from the shipping, which often supplies examples of tropical diseases. Several of the local medical men are very favourable to the scheme, and Sir Andrew Clark, Professor Gairdner of Glasgow, Professor Foster, Dr. Macalister of Cambridge, and many others have expressed their hearty approval of the enterprise. Professor Gairdner has gone so far as to consent to distribute the prizes and certificates, and to deliver an address on "Medical Teaching" at the closing ceremony of the college on Saturday, the 27th inst. Considering the crowded condition of the class-rooms and wards in Edinburgh and Glasgow, it is surely possible to attract students in sufficient number to make a respectable start, if only the money be forthcoming and the staff be carefully and wisely selected. The Universities (Scotland) Bill, 1885, contains a clause allowing St. Andrews University to affiliate colleges in other towns; and if Dundee can only show a good reason for the existence of its medical school, and good, honest work, the Executive Commission which will be appointed under the Act will hardly be able to pass over its claims to recognition. It may interest our readers to know that this is not the first time the scheme has been broached, and that it, or something like it, was suggested in the columns of the *Dundee Advertiser* by a retired Edinburgh surgeon, the late Dr. Watson-Wemyss, of Denbrae, St. Andrews, as long ago as 1872.

ANOTHER KIMBERLEY SQUABBLE.

WE have received from a correspondent a long series of newspaper reports and letters concerning the financial position of the Kimberley Hospital. A short time since "small-pox" and "pemphigus" were the daily pabulum with which the medical philanthropists nourished their personal friendships and antipathies. Now the scourge has vanished or abated, and fresh means of airing their grievances have been supplied to the "happy family." To an unbiased observer it is difficult to ascertain the exact truth where rival statisticians openly accuse each other of falsifying facts. "Pro bono Publico" says the average cost per head per annum at the Kimberley Hospital is £132. "Truth" puts it at £95 19s.—a greater difference than can be explained by what physicists term "errors of experiment." To our mind, it is scarcely possible to apply the working results of a British hospital such as the Royal Infirmary at Glasgow, as quoted by "Pro bono Publico," to the elucidation of the question of reasonable expenditure at the Kimberley institution. Distance may lend enchantment to the view, but it cannot be credited with enhancing clearness or accuracy of vision. The social and domestic circumstances obtaining in a distant colony, with which the paths of communication are difficult and few, are so widely different from what they are "at home," that no safe ground is afforded for comparison of the relative merits of apparently similar phenomena. It is not so much a matter of importance that the Kimberley Board of Management spends "four" or "two and a half" times as much on their establishment as suffices to liquidate the expenditure of a Scotch hospital, as it is to show that due attention is paid to economy and efficient administration. Hard times bring discontent, and Kimberley has during the last few years witnessed a rapid decline in her commercial prosperity. The hospital tax, which not long ago yielded something like £10,000 per annum, now provides only a little more than half that sum. But whilst the receipts have fallen short of the accustomed tale, the expenditure has not undergone a corresponding fall. There seems reason to fear, however, that certain abuses exist which might easily be remedied by zealous co-operation. If, as we are informed, the existing staff have the entire control over the medical and surgical appointments, we must enter a protest against the usage; but from our reading of the official reports we cannot convince ourselves of the accuracy of certain statements that have reached us. There is one point, however, on which seemingly all parties are agreed—viz., that the visits of the consulting surgeons are extremely irregular. This arises rather from the nature of the appointments than from laxity of discipline or want of interest on the part of the honorary officials. Either a definite number of beds should be apportioned to each officer, or all the patients should be seen by the surgeons in rotation. As regards the death-rate, which at first sight appears appalling, allowance must be made for the fact that of 189 natives who died in the hospital in 1884 eighty-six were "moribund when admitted." We should like to see a tabulated account of the fatalities from preventable diseases before too severely criticising the existing sanitary arrangements. One circumstance narrated in the resident surgeon's report stands in glaring prominence—viz., the prevalence and severity of venereal disease among the male community. The females, presumably, do not go into hospital, but wander free, moving centres of infection, and yet no provision is made for isolation of the contaminated. Cases of gonorrhœa, and syphilis in all stages, are mingled indiscriminately with patients suffering from such injuries and diseases as are commonly met with in a well-appointed hospital. Nor does the evil end here; for the ordinary female nurses have to attend to the general wants of all alike, obviously exposing themselves and others to the chances of accidental inoculation; to say nothing of the moral degradation which such a vicious system entails. Kimberley wants lock hospitals and a rigorously enforced Contagious Diseases Act. Lastly, as concerns the custom of allowing ministers of religion to enter the wards of the hospital at all hours without let or hindrance, we cannot but offer a word of admonition and advice. We yield to no one in advocating and insisting upon the utmost freedom being accorded to patients in the choice of their religious advisers; but there is a season and a place for all things, and in this instance, as it appears to us, it is not wise nor expedient that a clergyman should be permitted to enter a sick chamber and find himself, perchance, in a situation that neither himself, the patient, nor the nurse would deem desirable, even though "the soul is more important than the body."

ERYSIPELAS IN PARIS.

A DEBATE upon erysipelas has been occupying several sittings of the Paris Academy of Medicine, and at the last meeting M. Verneuil summed up the conclusions arrived at. "In Paris, a few years ago, erysipelas was very common and very fatal, especially in surgical practice. The antiseptic treatment of wounds has considerably diminished in frequency and gravity, without, however, succeeding in causing its complete disappearance; the erysipelatous endemic remains, ever ready to reproduce its epidemics, brief and restricted no doubt, but still involving a certain number of victims. It occurs in two distinct foci, the hospital and the town, which reciprocally infect each other. Antisepsis, powerful and efficacious in the nosocomial area, is almost impossible to be applied as a prophylactic measure in the urban area, that is and will long be contaminated; so that, after having by every precaution purified a hospital or a ward, a single case imported from the town suffices to again introduce the poison. It would be easy to prove that every year in our hospitals a certain number of patients attacked with other affections, sometimes trivial, succumb from the contagion of cases of erysipelas admitted from outside. In spite of the immense value of antisepsis, it is not applicable to all cases, and cannot prevent the introduction, dissemination, and multiplication of heterocthonous erysipelatous germs. Nor can it prevent these germs, cultivated and multiplied in hospitals, being subsequently reproduced in the town. In order to prevent re-infection of insanitary places and the dispersion of germs, to destroy the evil at its root, there is only one serious plan—viz., the isolation of cases developed within the hospital or introduced from the town. The establishment of isolation wards for the erysipelatous is a necessary measure, strenuously demanded both by science and humanity. Consequently, the Academy of Medicine demands of the authorities the immediate formation of such institutions." After some discussion, MM. Verneuil and Trélat were authorised to bring up a further report to the next meeting of the Academy.

WOOLWICH REFUSES TO APPOINT A MEDICAL OFFICER OF HEALTH.

A COMMITTEE of the Woolwich Local Board has now drawn up an elaborate report in answer to the statements made some five months ago by the Local Government Board's inspector, Mr. Spear, who strongly advised that the local authority should appoint a medical officer of health. The committee entirely dissent from Mr. Spear on the question of the advantage that would be gained by the appointment of such an official; they point out that the town is as healthy as other neighbouring towns where, of course, there are medical officers, and that the drainage, both public and private, and the overcrowding are quite as well under control as in those localities. With regard to disinfecting arrangements, they mention triumphantly that though "they have caused inquiry to be made as to the methods adopted in parishes and districts where medical officers of health are engaged, the result of such inquiry is not such as to induce your committee to recommend any alteration of the existing system in this parish. The adjoining parishes, where medical officers are engaged, have availed themselves of the system adopted by this board, and have not suggested any alteration." They also say that they are strongly of opinion that by putting in force the powers which the board possesses in sanitary matters, with the valuable assistance which they have at all times derived from the medical practitioners of the town and district, they will be enabled to fulfil all the duties incumbent upon them without a medical officer—they are always ready to appoint one temporarily for a special purpose. If they can be shown that other districts are better managed than their own because of the existence of a medical officer, they will be happy to reconsider the question; but Mr. Spear's report has failed to carry conviction to their minds.

SECTARIAN SISTERHOODS IN HOSPITALS.

PUBLIC opinion is beginning to be offended with the encroachments of religious sectarianism in hospital management. The evil is not a new one, and, as might perhaps have been expected, it has manifested itself on more than one occasion in an acute form in the proceedings of nursing sisterhoods. Belief and propagation of belief very commonly go together, and the sisters who have sought at the bedside to inculcate their particular tenets have acted no doubt in accordance with the teaching of an over-mastered conscience. Among themselves, moreover, they have not been wanting in an intolerance which excludes from membership, even in the secular work of their essentially liberal calling, every qualified nurse who does not assent to their peculiar and often very incomplete views of religious truth. The term "sisterhood" would seem to imply the exhibition of two principles: one, that skilled nursing is valuable; the other, that its efficacy requires the presentation by nurses to the sick under their care of one particular form of religion, and no other. The sister's perception of divine light is to serve for the whole ward: it does not matter that the supporters of hospitals or the patients represent every possible shade of belief, and that they in common desire that no restriction shall be placed on private judgment in such matters. Clergymen, lay teachers, friends, indeed, may enter and depart, but the constant spiritual atmosphere of the hospital must be maintained at a certain assumed purity, and that is to be regulated by the opinion of the nursing staff under their Sister Superior. If this is not the meaning of the doctrinal tests applied by these ladies, what is their meaning? The question, though extra-medical, is well worthy the consideration of hospital authorities and their supporters. The anomalous proceedings of such sisterhoods have long ago passed the bounds of our own approval. If they are persisted in, we can foresee only injury to the nursing body themselves, and difficulty, on other grounds most undeserved and regrettable, to the hospitals. Disease takes no note of creed; its treatment implies none, excludes none. We shall gain nothing by seeking to controvert the natural plan, or the law of liberty and of fairness, which distinguishes true Christianity above every other faith.

A CUBAN CURE FOR NEURALGIA.

DR. ANTONIO L. ESPERON reports in the *Crónica Medico-Quirúrgica* of Habana, Cuba, two cases of neuralgia treated with parthenin, a drug extracted from a plant known in Cuba as "bitter broom" (Escoba amarga). The first was a married woman, aged twenty-three, who, after an abortion, became subject to severe pain at the menstrual periods affecting the iliac fossæ. In one of these attacks, when the author attended her, he found morphia, chloral, and bromide of potassium useless, but that relief was afforded by quinine. In a subsequent attack, when there were rigors, headache, pyrexia, and furred tongue, ovarian neuralgia was diagnosed. A subcutaneous injection of morphia was given, and afterwards one-sixth of a gramme of parthenin every two hours was ordered. At the next visit it was found that after an hour the effects of the morphia began to pass off, and the pain had returned. The medicine had not been administered. After three doses of the parthenin the pain disappeared, and did not return. The second case was that of a coloured woman with severe coccydynia. Morphia only relieved this temporarily, but after a few doses of one-sixth of a gramme of parthenin in pills the pain permanently left her. The writer has also employed parthenin in many cases of facial neuralgia with great success. He believes that it is especially indicated in neuralgias of malarial origin.

THE TRAFFIC IN GIRLS.

THE *Pall Mall Gazette* of June 16th contains a report of a meeting held in Whitehaven to consider means for repressing the traffic in English girls. With the general purpose of such meetings no one who values the welfare of his kind can refuse to sympathise. The existence of the traffic we have referred to may be taken as proved by recent examples. Indeed, it is in the nature of the immoral commerce which it serves that such a traffic should flourish wherever it is allowed to do so. We must, however, in order to accomplish the removal of this evil, be sure first of all of the accuracy of our details respecting it. One statement in the report we have referred to is quoted from Mr. James B. Wookey, and bears absurdity on the face of it. It is gravely said that "in eight years, in three London hospitals alone, twenty-seven thousand children between the ages of eleven and sixteen have been treated for terrible diseases." This is an exceedingly vague statement. What are terrible diseases? Mr. Wookey does not appear to have defined his meaning. If he means by this term to describe venereal disease, the obscurity increases. Diseases of this class unfortunately do not as a rule present an aspect sufficiently terrible, otherwise there would be a more general and wholesome dread of them. Even when we allow that their insidious action ought to be deterrent, if it is not, we are no nearer the mark. We do not know the nature of that large body of cases, and we may say with certainty that acquired syphilis has no connexion whatever with the majority of them. The system of case registration at the London hospitals would probably not suffice to establish the accuracy of so large a statement with regard to out-patients, and it is known that no such number of venereal cases have been treated within the wards of any three hospitals. Those who would protect the youth of either sex from its most dangerous folly must be very careful of their facts and regular in their methods. They will then, but only then, carry with them the opinion of the country, and may be as unsparing as they have good reason to be towards the common enemy.

THE PRINCE OF WALES AND THE WORKING CLASSES.

THE Heir Apparent to the Throne is so worthily treading in the footmarks of his father that scarcely a week passes which does not supply some opportunity for an effort on the part of his Royal Highness for the public good. On Tuesday the Prince of Wales pleaded on behalf of an undertaking which is designed to supply the residents of Whitechapel with a popular place of resort for purposes of healthful exercise and improvement. There can be no question as to the need and value of this benevolent enterprise. Meanwhile we venture to hope it will not in any way clash with the undertaking in progress, at the instance of the Earl of Shaftesbury, in the same district. It can scarcely be possible that the two good and useful works promoted by philanthropists of all parties and schools should clash, but we venture to suggest that Sir Edmund Hay Currie should explain the facts more fully, especially after the letter of Mr. Charrington in *The Times* of Wednesday.

REMOVAL OF TUMOURS FROM SCARPA'S TRIANGLE.

M. KIRMISSON recently contributed a paper on the removal of tumours from Scarpa's triangle to the Société de Chirurgie de Paris. He points out that whatever be the nature of the tumour, the steps of the operation must be influenced by the anatomical relations of the part, and especially by the proximity of the tumour to the main vessels of the limb. He recommends the operator to free the tumour on its outer side first, and gradually to work towards the general sheath, leaving this part to be dealt with last; this is, of course, only a well-established surgical practice in all similar cases. When the tumour is closely connected with the main vessels, its removal may be complicated with one of three conditions—the vessels may be exposed, the vein may be wounded, or the vein and artery may both be divided. Wherever practicable, the sheath of the vessels should not be opened, but exposure of the vessels in the wound may be accepted as free from special danger if the wound be kept aseptic and devoid of inflammation. What line of practice is to be followed when the femoral vein is wounded? Some surgeons, among them Kümmel and Kraske, have advised that both the artery and vein should be ligatured; but such a practice is to be wholly condemned. To tie the artery is greatly to complicate the case and increase the danger of gangrene. Experience has proved the danger of lateral ligature of large veins, and the best practice is to put a double ligature on the vein above and below the puncture and divide the vessel between. Where the tumour is found to invade the vascular sheath to such an extent as to necessitate the division of both vessels, if it be entirely extirpated three courses are open to the surgeon—to remove the tumour partially, to ligature the vessels above and below, or to amputate the limb. Ligature of the femoral artery and vein above the origin of the profunda branch presents such great danger of subsequent gangrene of the limb that it is never justifiable. Should the tumour be situated lower down, so that the ligature would leave the deep femoral vessels to carry on the circulation, it should be excised completely and the main vessels tied. This may be done with greater confidence in young people than in those *past middle life. Should gangrene come on, amputation* must be performed. In the cases where this practice cannot be followed, the incomplete removal of the tumour—unsatisfactory as it is—is the wisest course to follow if any operation has been attempted. Amputation at the hip-joint is too dangerous an operation to be undertaken in circumstances which render recurrence of the growth, either locally, or, in internal organs, extremely probable. The best course to follow in such cases, if they be recognised before operation, is not to attempt removal, but to use palliative measures only.

THE FLOWER MISSION.

SOME months ago we published an appeal on behalf of the Flower Mission. At that time the flower season was just closing, and our remarks had therefore a somewhat retrospective meaning. Now we have reached the middle of a luxuriant summer, and it may be well, while the subject of hospitals is before the public eye, to place before it also the claims of this appropriate, inexpensive, and most acceptable form of contribution. The needs of the sick in hospital in their various degrees of suffering do not require to be pressed anew. That the gifts of flowers which they receive are appreciated there can be no doubt. They like the attention implied in such an act of kindness, as who would not? Probably they do not fail to note any care that may have been taken in selection on the part of those who bring these simple gifts. We do not mean that the choice of suitable flowers implies any laborious discrimination, but some taste, nevertheless, has to be used in avoiding extremes of odour and colour. In making presents of this kind, whether they come from the field, the garden, or the hothouse, it should not be forgotten that the simplest, and it may be the most usual and familiar, are often the most esteemed. There is also a necessary and inartistic method in giving. It is best to give without saying much. A word or two will go a long way, for the flower illustration speaks for itself, and has the advantage that it wearies no one.

RUPTURE OF THE PERINEUM.

WE have before us an interesting paper by Dr. W. P. Manton of Detroit, Michigan, reprinted from the *American Journal of Obstetrics*, advocating the practice of episiotomy, or the lateral incision of the perineum, for the prevention of perineal rupture. This operation has not been so favourably regarded by authorities in this country as by some German obstetricians. Dr. Lusk of New York, in his admirable book on the "Science and Art of Midwifery," while advocating various devices for regulating the passage of the head over the perineum, says that "when rupture seems inevitable," the physician is justified in making lateral incisions; but he adds that as every wounded surface in childbed is a source of danger (by risk of infection), episiotomy should never be performed so long as hope exists of otherwise preserving the perineum. He adds the somewhat severe remark: "It is essentially the operation of young practitioners, the occasions for its employment diminishing in frequency with increasing experience." We will leave Dr. Manton to settle this difference with his senior colleague in the obstetric art. He is young enough, perhaps, to feel the force of Dr. Lusk's criticism, but he does not speak without a large experience. He shows the great frequency of the occurrence of ruptured perineum. He denies that infection is more frequent after episiotomy. He has notes of 957 primiparæ in the Vienna clinic, and in only two of the cases did posterior laceration occur after episiotomy. These were both forceps cases. Professor Credé gives an analysis of 1000 cases of primiparæ, showing that only 2·9 per cent. were ruptured after episiotomy. We *confess to still feeling a considerable objection to the operation*, and to doubting the necessity for its frequent use. We can easily imagine it performed hastily and to the neglect of the ordinary methods of supporting and saving the perineum, which are tolerably effective, at least as against bad ruptures. In forceps operations especially, where, on Dr. Manton's own showing, episiotomy does not necessarily save from rupture, many perinea would be saved if the operator would seek the assistance of a neighbouring practitioner, whose chief duty it should be to support the perineum while the head is passing. It is very difficult for the accoucheur using forceps to execute the double duty of extracting with one hand and supporting the perineum with the other, and it is in these cases that the most serious lacerations occur.

THE METROPOLITAN ASYLUMS BOARD.

AT the usual fortnightly meeting of the Metropolitan Asylums Board, held on the the 20th inst., a letter was read from the Local Government Board authorising the purchase from the Admiralty of the ships *Atlas* and *Endymion*, the prices to be paid being £8400 and £6500. A report was also read from Dr. Birdwood, the medical superintendent of the hospital ships, *on the subject of the non-alcoholic treatment* of small-pox patients. He stated that, from being a firm believer in the treatment of small-pox patients by alcohol, he had, at the suggestion of his colleague, Mr. Bott, gradually reduced the administration of alcohol until now spirits and wine had been disused altogether, and, with a larger average number of patients, only 318 pints of beer were given in a week, whereas formerly, in addition to wine and spirits, nearly 9000 pints had been given. Dr. Birdwood added that he had proved alcohol to be injurious in the treatment of small-pox; hence he had ceased from prescribing it, except in moderation, for convalescents. The report was ordered to be be entered on the Minutes.

CORONER'S INQUEST IN WALES.

ON Friday, May 29th, an alleged murder was committed and suicide attempted at Aberystwyth. The facts relating to the event seem not to have been disputed, and we may at once say that the decision of the magistrates to send the case for trial on the capital charge was fully warranted by the evidence. At the request of the Mayor, Mr. Rees Davies repaired to the scene of the tragedy, where he found the victim quite dead, with blood issuing from the mouth and what appeared like a bullet wound in the left upper jaw. He did not make an exhaustive examination, for in truth he had no legal right to do this unarmed with a coroner's order, as the corpse was in the official custody of that functionary. *At the inquest* Mr. Davies is reported to have said that he believed "the wound in the face was enough to cause death." Before the magistrates he gave a less decided opinion, and it was at this juncture that there appears to have arisen the notion, that in the interests of justice a post-mortem was desirable—nay, even necessary. But the jury having delivered their finding, the coroner had lost his jurisdiction in the case, and the justices having no power to issue the necessary instructions, an appeal had to be made to the Home Secretary for permission to reopen the inquiry into the mode of death. Curiously enough, the coroner (Mr. Rowland), who seemed to agree with the jury that a *sectio cadaveris* was not needed, himself conducted the investigation after his court had declared itself satisfied. Mr. Rowland, in his "true version of the case," published in the form of a handbill, seeks to justify his course of procedure by saying that Mr. Davies, in answer to a question by a juror, deposed that "the wound was enough to cause death," whilst afterwards he qualified the statement by adding the words, "if the bullet had pierced the brain it would do so." As yet, however, there was wanting proof that the brain had been injured by the missile. Presumably the wound was enough to account for death; probably it was the bullet that caused the wound; but surely stronger evidence would be required to obtain a conviction. In the first place, it was mere matter of speculation where the bullet was lodged, and, consequently, whether the wound inflicted by it was the cause of death. Mr. Rowland should have issued an order for a post-mortem examination before the inquest was opened, or, to say the least, before it was closed. It was scarcely in keeping with the dignity of his office to personally conduct the search for evidence which should have been placed before him for his judicial consideration.

DIAPHORETIC TREATMENT OF NEPHRITIS.

N. HESS, having made a number of observations on the treatment of nephritic patients by wet packs, hot baths supplemented by wrapping in blankets, and hot-air baths, draws the following conclusions:—(1) The least rise of temperature occurs with packs, the greatest with hot baths. (2) While the temperature is found to sink still further twenty minutes after the pack, it remains at the same height for an hour after both the other methods of treatment. (3) After water baths the temperature regains its original height more slowly than after air baths. (4) During the pack the pulse becomes slower; during both water and air baths, on the contrary, it is quickened for an hour afterwards. (5) Under the influence of the pack respiration is moderately quickened; during both water and air baths it is still more quickened, but subsequently returns to its normal rate more rapidly than after the pack. (6) The most powerful sudorific effects are produced by hot baths, the least powerful by packing. (7) Though the baths are more stimulating, packing soothes the action of the nervous system, brings the patients on better, and produces a subjective feeling of improvement afterwards. (*Vrach*, quoted in *St. Petersburg. Med. Woch.*)

SICK NURSING.

DR. DUCKWORTH's admirable inaugural lecture on "Sick Nursing essentially a Woman's Mission" should be read by all women who aim at being nurses whether in private or in hospitals. The calling of the nurse is indeed a responsible one. It is growing rapidly in public estimation. Hitherto there has been much prejudice against regular nurses, founded chiefly on an impression that they are unsympathetic, that they require more attention than they give, that they are not to be always trusted alone and in the night with those disabled and helpless, and on the experience that many nurses are too fond of stimulants. These faults have certainly not always been absent in professional nurses who come to the sick house as if they came "to be ministered unto, and not to minister." The nurses who take Dr. Duckworth's address for a guide will obliterate all such impressions and raise their vocation to a high pitch of esteem among men whether rich or poor. He is plain-spoken as to the virtues and the qualities of a good nurse, and makes effective allusion to some of the old worthies of the calling in St. Bartholomew's: one to Sister Hope, who came in as a patient and had to lose a leg by amputation, but who survived and became a Sister and remained in faithful and untiring service for forty years. He also mentions Sister Elizabeth, of whom Dr. Jeaffreson once said to Dr. Duckworth, "I have only to say to Sister Elizabeth, 'That case is a bad one,' and she will never hold her hands day or night to save it if possible." The lecture is worthily dedicated to Sir Sydney Waterlow, who has the ambition to make Bartholomew's as famous a school for nurses as it has been for medical men.

SUPRA-PUBIC LITHOTOMY.

IN the June number of the *Revue de Chirurgie* M. Montprofit records a case of supra-pubic lithotomy successfully performed by M. Terrier early last year. The patient was a man twenty-nine years of age, who had had urinary troubles for six years. He was emaciated and very weak and exhausted when he came under treatment, and the stone was considered to be too hard and large for perineal lithotomy. The suprapubic operation did not present any difficulty, and an irregular stone 1½ in. (40 millimetres) in diameter was removed. The subsequent progress of the case was interrupted by a bad bedsore over the sacrum, by phosphatic deposits in the bladder, and by the formation of two scrotal abscesses just beneath the penis. In spite of these complications, the man ultimately made a complete recovery. No mention is made of the weight or composition of the stone, two serious omissions in the record of a case of lithotomy.

CHOLERA IN SPAIN.

THE King of Spain has yielded to the representations of his responsible advisers and has abandoned his intention to visit the cholera-stricken districts of the country, but the Government has decided that three members of the Cabinet shall proceed to Murcia, where, according to the last return of June 21st, there were the previous day 98 cases in the city and 39 deaths, the total number of cases and deaths in the whole province being 325 and 131 respectively. Cholera is still extending in Valenc a, where in twelve hours there were five deaths in the city and three deaths in neighbouring towns. A few deaths continue to occur in Madrid, causing the greatest excitement to the tradespeople, who have draped their shops in black as a protest against the official declaration of the existence of cholera. The isolated cases which are reported in the villages adjoining the capital are doubtless the forerunners of local epidemics.

VARIX OF THE UPPER EXTREMITY.

AT a recent meeting of the Société de Chirurgie of Paris M. Bousquet exhibited a patient who had enormous varices of the right upper extremity. The veins had been enlarged since birth, and had not caused any functional disturbance of the part. There were no varices in the lower limbs or in the spermatic cord. Other examples of varix in the upper limb are recorded by various writers. Brodie refers to a case of considerable varix of the veins of the forearm which followed upon inflammation and obliteration of the median-cephalic and cephalic veins. These cases are analogous to many others recorded by himself and of almost daily observation, where, from the presence of an aneurysm or other form of mediastinal tumour, the superior vena cava or one of the innominate veins is obliterated. Three years ago Mr. Thomas Smith showed at the Clinical Society of London a girl who had considerable dilatation of the superficial veins of the hand and forearm. The varix had developed after a burn, and was associated with a similar change in the arteries of the part. One of the most famous of these cases is that recorded by Petit. The varix was situated at the bend of the elbow, and Petit performed venesection upon it 150 times, as the patient was so fat that no other vein could be found for the purpose. Velpeau states that he had seen two persons with the arms, forearms, and hands covered with varicose tumours.

BRITISH DENTAL ASSOCIATION.

It is intended to hold the annual meeting of this Association at Cambridge this year on August 27th, 28th, and 29th, under the presidentship of Mr. Richard White, of Norwich, and an ample programme is already provided. The university authorities have been most cordial in their recognition of the Association; the natural science class-rooms have been placed at the disposal of the committee, and the debating hall of the Cambridge University Union has been lent for the chief meeting place. This is the first time in the history of the Union that such a concession has been made, and the members of the Association will be, in addition, honorary members of the Union for the time of meeting, a most courteous and liberal acknowledgment on the part of the authorities. The Master and Fellows of Caius College have generously offered sleeping accommodation for some of the chief officers of the Association, and besides this, they have given the use of their large dining hall for the annual dinner. A garden party will be held in the grounds of one of the other colleges, and altogether the members of the British Dental Association may congratulate themselves upon the very advantageous circumstances in prospect for their meeting in this most interesting and quaint old town.

DR. FERRAN'S INOCULATIONS.

The interesting account given by our correspondent last week of the inoculations for cholera now being so extensively practised by Dr. Ferrán, may be supplemented by the fact that the Spanish Government, acting upon the recommendation of the commission sent to report on the subject, has authorised the continuance of these "experiments." In a letter to M. Pasteur, whose views upon the protective character of inoculation with attenuated virus form the basis of the practice, Dr. Ferrán says that, although actual immunity may not be obtained, still his vaccinations will alleviate any attack which may occur subsequently. As a result of the official sanction, we may expect to hear of a very considerable increase in the number of inoculations.

THE TAIL OF THE HUMAN EMBRYO.

At a recent meeting of the Paris Academy of Science, M. H. Fol gave an account of his investigations upon the tail of the human embryo. At an early period of development—about the fifth or sixth week—there are several distinct caudal vertebræ behind the sacrum. The embryo is then from nine to ten millimetres long, but when it attains a length of twelve millimetres the total number of vertebræ is already reduced from thirty-eight to thirty-five. At a later stage, when the embryo measures nineteen millimetres, only thirty-four vertebræ can be distinguished, the thirty-fourth being obviously made up by the fusion of the four terminal ones.

We are glad to learn that the price of hydrochlorate of cocaine has been considerably reduced, and may now be obtained at the principal chemists for 1s. per grain. We are informed that there is a probability that in the course of a few days the cost of the anæsthetic may be still lower.

Writing in the *Deutsch. Med. Wochenschrift* for the 18th inst. upon the Policlinic for Diseases of the Teeth and Mouth in the newly established Dental Institute of Berlin University, Professor Busch states that hitherto only two cases of death attributed to poisoning by nitrous oxide gas during inhalation for anæsthetic purposes have been recorded. Both occurred in 1884: one at the Dental Hospital in London—a man who was having a tooth removed preparatory to excision of cancer of the tongue. In this case a tumour was found post mortem growing from the skull and compressing the brain; therefore Dr. Busch does not think death can fairly be attributed to the gas. The other case occurred in the practice of a Paris dentist; but as no record was obtained of any post-mortem inquiry, Dr. Busch suspends his belief in this case being due to the gas. The mere fact of death during the narcosis is not sufficient to attribute the fatal result to that cause.

Our contemporary the *Spectator*—which, by the way, is always liberal in its bestowal of praise on the medical profession—has lately been discoursing on the possible advent of cholera to this country. After indicating the probable path of transit, it proceeds to criticise the modes in which the disease spreads, ridiculing quarantine and sanitary cordons as "useless precautions." So far it follows closely in the groove of safety and accuracy; but when it comes to treatment, its enunciations are brief and a little startling to those who are accustomed to read in lay as well as medical periodicals of so many "tips" for cholera. Stimulants and astringents are all ignored, and expressedly cast on one side as useless, for "the only remedy as yet found efficacious is opium." Has the learned editor heard of "cholerisation?"—if not, we commend to his notice the experiments now being conducted by Dr. Ferrán.

From the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of May, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies exhibited a further improvement as regards organic matter, the average proportion being even less than in any month of last year. All the waters were clear and bright on delivery. Of the water drawn from the Lea, that distributed by the New River Company was, as regards organic matter, second only to the best deep-well water; whilst the East London Company's supply contained rather more organic matter than the Thames waters. Both samples were clear and bright.

Messrs. Crookes, Odling, and Tidy, in their report on the same subject, state that the character of the water supplied to the metropolis during the past month has been in every respect excellent.

The German Imperial Board of Health is about to publish a journal every week for the record of sanitary statistics, reports, records, and papers connected with the department. The scientific "Arbeiten" will be continued, but in the form of supplementary parts of the journal, and issued from time to time. The journal is to appear next month, and will be published by J. Springer, Berlin.

The Port of London Sanitary Committee, finding their hospital accommodation at Gravesend insufficient, have resolved, under the advice of their medical officer, Dr. Collingridge, to erect hospital tents for the treatment of cases of small-pox. One has already been put up by Messrs. Edgington and Co. within twelve hours of the receipt of the order.

IN the Medical Faculty of the Vienna University, Drs. Ultzmann, Wölfler, Mauthner, and Hofmokl have been nominated to extraordinary professorships. Dr. Ultzmann has made important contributions to surgery, especially in the subjects of lithotripsy and lithotomy; Dr. Wölfler, is well known as Prof. Billroth's assistant, and for his writings on "Excision of the Pylorus" and other surgical subjects. Dr. Hofmokl has also been engaged in teaching surgery for some time. Dr. Mauthner has done good work in chemical science. The *Allgemeine Wiener Medizinische Zeitung*, while stating that it does not as a rule approve of increasing the professoriate by extraordinary appointments, is bound to admit the justice of the present appointments, and he believes the promotions will be welcomed by the profession.

THE Chair of Helminthology at the Royal Veterinary College has, we understand, been vacated by Dr. Cobbold, F.R.S. It is not probable that any successor will be appointed in his place, as no inconsiderable part of the subject will naturally be held to fall to the occupants of the chairs of equine and cattle pathology respectively. The question of parasites, however, in relation to epizootics is of very great extent, and it is one to which Dr. Cobbold devoted a great deal of time and research. The destructive effects of the strongyloid worms in particular were thus brought very prominently into notice.

ON the motion of its President, Professor Guido Baccelli, the Royal Academy of Medicine in Rome unanimously admitted as honorary Fellows Sir Guyer Hunter, Dr. Thorne Thorne, Sir Joseph Fayrer, and Dr. T. Lewis, the representatives of Great Britain and British India at the recent International Sanitary Conference.

AT the University of Berlin the First Clinic, formerly under the charge of Professor Frerichs, is now relegated to Professor Leyden. For the other clinical chair the Faculty have nominated Dr. Gerhardt of Wurzburg in the first place, and Dr. Leube of Erlangen in the second.

THE Local Government Board has recommended to the Public Loan Commissioners a loan of £20,000 at 3½ per cent. interest for the purpose of the new drainage scheme at Romford.

THE Brentwood Sanitary Committee has decided to provide a hospital for persons suffering from infectious disease.

REPORT
OF
The Lancet Special Sanitary Commission
ON
MARSEILLES AND TOULON.

No. II.

AT Toulon the sanitary defects of Marseilles are repeated, and even considerably accentuated. The great maritime and arsenal town of France does not even possess an adequate water-supply. A large number of houses have private wells, where the water is constantly contaminated; and but very few can boast of a closet. The street is the sewer, and the water in the gutters serves the double purpose of carrying away the sewage and of cleansing the houses. Women can be frequently seen in the streets with mops and towels, dipping these into the gutter, and then employing them to scrub the floors or the walls of their homes. Here and there, in the recess of a wall, may be noticed a *tinette* placed on the same level as the pavement. This betokens that the house possesses the uncommon luxury of a closet. A carelessly closed rough door only partially conceals the pail from view, and underneath the door the overflow of the *tinette* may be seen and smelt as it slowly oozes out, and, like everything else, finds its way to the gutter. In one of the streets, after passing by two or three of these *tinettes*, we watched a woman come out of a house, which evidently had no closet, and empty the foul contents of her *passares*, or deep night-stool, into the gutter. At the same time, and barely twenty yards further down the street, another woman, singing joyfully over her domestic duties, proceeded to dip a house-cloth into this gutter. When it was well saturated with sewage, she took it in-doors, where she used the moist cloth to wipe over the entire surface of the dining-room table. In due course, bread, fruits, and other edibles were laid on the table, though it was still damp with what was literally the sewage of the street. In another thoroughfare a dam had been made across one of the gutters, and in the water thus accumulated the bricks employed for the building of a house were carefully soaked; every brick had therefore absorbed a certain amount of sewage matter before it went to build the walls of that dwelling.

The condition of the houses in the narrow crowded streets where the cholera made the greatest ravages is in every respect about as bad as can be conceived. In the Rue St. Claire, Rue Miséricorde, Rue des Bonnetiers, Rue Hoche, &c., we visited several houses, and in several instances the back rooms were devoid of light. Some of these served the triple purpose of kitchen, bedroom, and scullery, and remained in a perpetual condition of impurity. On the other hand, in the new and wealthy quarters of the town there is little or nothing satisfactory to note from a sanitary point of view. The houses have closets, it is true, and have even adopted the Parisian system of cesspools; but these are so badly built that they infect the surrounding subsoil, and we had pointed out to us one of the handsomest and most modern among the new houses which is never exempt from typhoid fever. Three separate outbreaks have already taken place in this stately and luxurious building, though several of the flats are not yet let. Next door there were two cases of cholera, and opposite a case of typhoid fever. Indeed, typhoid seems to be more frequent in the new portion of the town, where cesspools have been built. Probably the healthiest houses in Toulon are the better class, but older dwellings, where there are no cesspools, but only movable pails without overflow, and where none but the water of the town-supply is used. Nevertheless, absolute safety cannot be found anywhere, because the entire subsoil is impregnated, and it is impossible to ward off the dangers created by the uncleanly habits and ignorance of the native population.

In the face of all these and many other facts, which the exigencies of space prevent our mentioning, the outbreak of cholera is only remarkable in so far as it does not occur more frequently and does not prove more fatal. That cholera is likely to revisit Toulon again and again there can be no doubt. That the high annual death-rate, officially estimated at 33·8 per 1000, is in a great measure due to preventable causes is equally obvious. That something effective will be done to remedy this disgraceful and barbaric state of affairs is not so certain. It should be easier at Toulon than elsewhere to bring about the necessary improvements. As a great maritime station, the Portsmouth of France, Toulon has a distinct claim on the State, but this claim has so far been an impediment instead of a facility; the local authorities expect the State to do all, or nearly all, that for which under other circumstances they alone would be held responsible. While the dispute continues between the State and the town as to who shall pay the cost of the improvements, nothing is done, and there are no signs as yet of any solution to this vexed question.

This has not, however, prevented the elaboration of extensive projects, and the scheme, presented by M. Dyrion, engineer of the town, has been approved by the Special Governmental Commission appointed to inquire into the matter. This official report is signed by Dr. Brouardel, President of the French Consultative Committee of Hygiene, and M. Bruniquel, Chief Engineer of the Ponts et Chaussées. The report emanates from the Ministry of Commerce, and proposes, in the first instance, that the waterworks of Toulon should increase their supply from 10,300 cubic metres to 17,000 cubic metres, and this under a pressure of 80 metres. At present the water reaches only the lowest levels. Then the report insists that each house should be supplied with trapped ventilated drains, provided with enough water to ensure their cleanliness. As Toulon is washed by an enormous quantity of storm-water heavily charged with sand, it would be difficult to build sewers capable of carrying away the rainfall. A surface drainage by gutters and the various rivulets of the district is best suited to this purpose; and, according to M. Dyrion's project, a separate canalisation of small pipes is proposed for the sewage matter. One pumping-station would suffice to deliver the whole sewage of Toulon with its 70,000 inhabitants at a spot situated near the Sablettes, to the west of the town. Here a sewage farm could be established, or else the outfall could be conducted straight into the sea. The pollution of various watercourses would then be prevented, for the neighbouring inhabitants would drain into the sewers. The sewers would be of iron, and the largest barely more than a foot in diameter. The foundations are so insecure that preference is given to iron, and it is proposed to use all the water coming from public fountains to feed automatic flushing tanks. On the whole, the scheme is an able combination of English and American systems of drainage, and would cost about £120,000. The further proposals to pull down some of the most insalubrious quarters, to build new broad streets, and, destroying some old fortifications, convert their sites into building land, involve a much larger outlay. All these schemes put together are estimated to cost £700,000, which is indeed a considerable sum for a comparatively small town.

Undoubtedly, if these schemes were fully applied, Toulon, now a focus of epidemic disease, would become one of the healthiest towns in France. If the financial difficulties were to be surmounted, there would, however, still remain the obstinate ignorance and indifference of the population. A system of house-to-house inspection enforced by Draconian bye-laws would be required to maintain the internal domestic cleanliness, which is the indispensable complement of a good system of drainage. In the meanwhile, Toulon is at least thus far in advance of Marseilles; it has submitted a complete scheme, and this project has been approved by the highest competent authority of France. The force of public opinion must now be exercised, so that these studies and projects may promptly lead to the fulfilment of promises long held out and as yet in no wise realised.

DR. RICHARDSON ON MEDICAL POETS.

IN the address on Medical Poets, delivered before the members and friends of the Students' Medical Society of Middlesex Hospital at their conversazione, on Thursday evening, Dr. Richardson claimed for medicine that she had produced three classes of poetic geniuses: the prose poets, the anonymous, and the actual. Like Apollo, who was God of Physic as well as of Music and Song, the followers of Physic had naturally and freely exchanged a common sentiment in both arts. It was impossible for men to go on for ages witnessing the griefs and joys of human life so intimately as men of medicine witness them without many being impelled to express themselves in song, and no single profession, consequently, had produced so many of the poet class. Claiming Virgil as belonging to medicine, and just touching with the lightest illustration on the exquisite melody of the Roman verse, the speaker observed that he should find in our country more material for his discourse than he could properly deal with in the brief period at his command, and should therefore refer to English poets only. We have had eleven poets of mark in this country; an unparalleled number as compared with the rest of the world. Treating of these by name, Dr. Richardson opened with Sir Thomas Browne, author of the "Religio Medici" who, in that immortal work, had not merely written one of the finest prose poems extant, but had given birth to and first modelled a sacred hymn, which was probably more frequently sung than any other in the English tongue. This was the evening hymn reconstructed by Bishop Ken from the hymn with which Sir Thomas Browne, after evening prayers, finished, he tells us, each day in preparation for sleep, and which, beginning with the stanzas,

> "The night is come: like to the day
> Depart not thou great God away,"

was read to the end from the "Religio Medici." Thence the transition was made to Sir Richard Blackmore, the voluminous poet, whose lines Dryden said were

> "Writ to the rumbling of his chariot's wheels,"

and on whom Pope in the "Dunciad" was even more severe. But, after all, Blackmore was a poet, and had he been content to compose one poem, "The Creation," instead of a dozen, he would have ranked very high amongst his class. From Blackmore the step was easy to Sir Samuel Garth, to whose life and character as poet and physician a tribute was paid beyond what has been usually accorded to him. The poem of "The Dispensary" and some translations from Ovid were warmly commended. From Garth the audience was led to Mark Akenside, from whose "Pleasures of Imagination" a quotation was culled; and from him to Armstrong, from whose poem on the "Art of Preserving Health" some special selections were given. After Armstrong the speaker came to dear old Oliver Goldsmith, one or two of whose lines and whose "Madam Blaise" were repeated with much animation. Following Goldsmith, Cotton of St. Albans, the author of the "Fireside" and other domestic pieces, was brought under notice, and after him Erasmus Darwin. On Darwin, the poet of all Darwinians and the poetic founder of all Darwinism, Dr. Richardson dwelt emphatically as on a man who, in every sense, was a gifted poet of the highest order as well as a philosopher, playing the same (or a better) part to Charles Darwin as that played by Plato to Aristotle. It is from this poet that the theory of the origin of species has its prime source. Erasmus Darwin shone better as a prose than as a rhyming poet. His poetic lines, long and monotonous, soon pall; but now and then, as in the little catch to "May," which was delivered in full, the facility for poetic music is well heard, so that possibly the poet rather failed from the character of the rhyme, the length of the poetic wave, which he usually selected, than from failure of genius. After Darwin, Crabbe was brought forward as a poet, bred to medicine and a faithful practitioner of it, and then a clergyman, equally faithful in that vocation. The poetry of Crabbe, always best when it is purely descriptive, shows the knowledge its author had gathered up in both of his professions, but in medicine most. The style—modest, forcible, musical—carries the reader along with it on the easiest and most graceful tide. In illustration, the speaker gave the audience the bright and well-told story of the boy who, found in a parish bound, was named by the sapient vestry Richard, because not one of the board rejoiced in that name, and Monday, because Monday was the day when

> "The unlucky peasant heard the stranger's cry,"

and who, sent to the workhouse to bear a youthful life of indignity, at last ran away, made a position in the world, and dying as Sir Richard Monday of Monday-place, immensely rich and honoured, left, in severe justice, to his native village

> "Two paltry pounds at every quarter day,
> At church produced for forty loaves to pay."

The last two poets brought on the scene were poets of our own century—John Keats and David Moir ("Delta" of *Blackwood*). To both warmest admiration was paid, and the incident of the two medical students, Keats and Stephens, sitting together when the famous first line of "Endymion"—

> "A thing of beauty is a joy for ever,"—

flashed across the mind of Keats, was naturally a medical student's incident to the letter.

From what Dr. Richardson further told his audience, it is clear that we have poets still amongst us: a leading surgeon who has written a drama, a physiologist who has tried his hand at the same art, a general practitioner who has "a budget of pieces," and a physician who has received a bardic distinction from the oldest of the old fraternities of the "order of nature." For these and their ultimate fate we must wait: they are not yet declared to the world.

The address closed with the brilliant lines of Keats, "A Draught of Sunshine."

NORTH-EASTERN HOSPITAL FOR CHILDREN.—On the 24th inst. a bazaar in aid of the funds of this institution, situated in the Hackney-road, was opened at the Cannon-street Hotel by the Princess of Wales.

HONG-KONG.

The annual report by the Colonial Surgeon on the health of Hong-Kong for the year 1884 contains some points of considerable interest. The death-rate of the European troops was 8·05, and of the Indian troops 24·24 per 1000 of strength. In the police force the mortality of the Europeans was 9·0, of the Indians 5·6, and of the Chinese 13·2 per 1000. In the Victoria Gaol the number of persons committed during the year was 4023, furnishing an average of 552 under confinement; among whom the admissions into hospital were in the ratio of 625, and the deaths of 5·45 per 1000—both very low. The weights of 87 habitual opium smokers were taken on their entrance and weekly for the first four weeks of their confinement in gaol, with the following results: 47 had gained, 28 had lost weight, and 12 had undergone no change at the end of the period. Mr. Ayres, the Colonial Surgeon, remarks, "I can find no special symptoms common to all opium smokers when deprived of the use of the drug; they are all ready enough to complain if there is *anything the matter with them, and are all* watched with the greatest care, and I find nothing to recall in anything I have stated in previous reports." One opium smoker died during the year, of general debility, being the first death among that class which has occurred in the gaol in a period of eleven years. In the Civil Hospital the death-rate among the cases admitted was—of Europeans 3·15, of coloured persons 1·24, and of Chinese 6·08 per cent.; in the gaol it was only 0·95 per cent. In the Tung-Wa Hospital, which appears to be one for the Chinese sick poor, and to be under the care of "the so-called doctors of the Tung-Wa Hospital," the deaths amounted to no less than 51·2 per cent. of the admissions. No information is given as to the diseases by which this excessive mortality was caused, but of the 755 that died, 291 are reported to have been moribund on admission. We trust that in future reports some detailed information will be given on this subject. In calling attention to this want of information, we think it but fair to Dr. Wharry, the superintendent of the Civil Hospital, to quote his remark: "A hospital report should include something in the shape of scientific observation, and might be expected to contribute something towards a knowledge of the diseases of the locality. This is out of the question, however, with one medical officer in sole charge of a general hospital of ninety-eight beds, a small-pox hospital of ten beds, and medico-legal work to perform as well." Mr. Crow, the Government analyst, gives a good account of the work done in the Government laboratory. The water-supply at Hong-Kong is obtained from two sources—the Pokfúlam reservoir, which is reported to be satisfactory, and various wells, many of which are unquestionably of a dangerous character. Some of them have been closed, but Mr. Crow is of opinion that this measure should be extended to a good many more of them. The analyses of bread and of milk afforded very satisfactory results. Four cases of suspected poisoning were examined: in two no trace of any poison could be detected; in the third opium was found; and in the fourth Mr. Crow was of opinion that the cause of death was the decoction of a drug known by the name of "Fooh-moon-keung," prepared from the Gelsemium elegans. "The Chinese have been aware of the poisonous action of this drug for centuries." The work done in the laboratory has been valuable, and we trust the Government may be induced to put the present temporary establishment on a permanent footing. It seems also very desirable that an addition should be made to the staff of the Government Civil Hospital, which under present arrangements appears to be decidedly overworked.

VOLUNTEER MEDICAL STAFF CORPS.

At the Mansion House, on Friday, June 19th, the Right Hon. the Lord Mayor in the chair, a public meeting was held to promote the interests of this corps. After stating the object of the meeting and recommending the movement to those present, the Lord Mayor was called from his position in the chair, which was subsequently ably occupied by Dr. Crawford, Director-General, Army Medical Department. The first resolution—"That this corps deserves the support of all classes of the community"—was proposed by General Gipps, C.B., commanding the Home District, and in a well-chosen speech was seconded by Sir James Hanbury, K.C.B., principal medical officer of the Home District, and supported by Mr. Furley. The second resolution—"That this corps is an essential part of the Volunteer force"—was proposed by Colonel Lumsden, London Scottish R.V., and seconded by Colonel Routledge, City of London, and supported by Sir William Mac Cormac. The third resolution—"That this meeting pledges itself to promote the interests of this corps, monetarily and otherwise"—was proposed by John Biddulph Martin, Esq., seconded by Sir Guyer Hunter, K.C.M.G., and supported by Colonel Shakespeare and General Lowry. All the speakers dwelt on the usefulness of the corps as a teaching element to young medical men, as well as a backbone and essential reserve to the Medical Staff Corps of the army. It was stated that the medical officers of the army had already grasped the importance of the movement, but that it would take a long time to educate the mass of civil practitioners to take their rightful places in public movements of this kind. Especially in this particular enterprise might it be expected they would come forward, as it is the first organised movement of the kind ever started by civil medical men in this or any other country.

The Volunteer Medical Staff Corps held its first church parade at St. Paul's on June 14th, being Hospital Sunday.

On Saturday, June 13th, the corps paraded at Woolwich Arsenal, when a course of instruction in loading and unloading ambulance waggons was gone through; as many as six waggons being available.

THE HOSPITAL SUNDAY FUND.

The following is a list of the principal contributions which have been received on behalf of the Metropolitan Hospital Sunday Fund since our last issue:—

St. Jude's, South Kensington (Rev. Dr. Forrest), £702 2*s.*; Regent-square Presbyterian Church, £121; St. Peter's, Cranley-gardens, £175 9*s.* 9*d.*; St. Peter's, Vere-street (with additions), £215; St. Mark's, Hamilton-terrace, £200 1*s.* 7*d.*; Bromley (Kent) Congregational Church, £100 7*s.* 3*d.*; Parish Church of Holy Trinity, Sydenham, £107 3*s.*; St. Paul's, New Beckenham, £103 4*s.* 3*d.*; Union Congregational Chapel, Islington, £101 1*s.*; Holy Trinity, Paddington (with additions), £183 12*s.* 6*d.*; Delta (a further contribution), £200; St. Peter's, Bayswater, £112 13*s.*; St. Stephen's, Paddington, £117 12*s.* 11*d.*; St. Peter's, Eaton-square, £458 3*s.* 3*d.*; St. Paul's, Wilson-road, £114 1*s.*; Portman Chapel, £168 12*s.* 5*d.*; St. Paul's, Avenue-road, £100 18*s.* 3*d.*; St. Paul's, Knightsbridge, and St. Mary's, Graham-street, £300 12*s.* 3*d.*; Holy Trinity, Upper Chelsea (Rev. Prebendary Eyton), £133 13*s.*; Wimbledon churches (St. Mary's, Christ Church, St. John's, and St. Mark's), £223 16*s.* 2*d.*; Grosvenor Church, South Audley-street, £107 8*s.* 8*d.*; St. Stephen's South Kensington, £179 14*s.*; St. Mary's, Bryanston-square, £118 12*s.* 6*d.*; St. Mark's, North Audley-street, £220 5*s.* 2*d.*; St. John's, Paddington, £177 5*s.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5426 births and 3129 deaths were registered during the week ending the 20th inst. The annual death-rate in these towns, which had declined from 21·1 to 18·6 per 1000 in the preceding four weeks, further declined to 18·3 last week, a lower rate than has prevailed in any week since the beginning of this year. During the first eleven weeks of the current quarter the death-rate in these towns averaged 21·2 per 1000, against 22·1, the mean rate in the corresponding periods of the nine years 1876–84. The lowest rates in these towns last week were 10·5 in Derby, 13·6 in Portsmouth, 13·8 in Wolverhampton, and 14·2 in Halifax. The rates in the other towns ranged upwards to 24·2 in Newcastle-upon-Tyne, 25·5 in Manchester, 25·5 in Blackburn, and 31·7 in Cardiff. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 520 and 429 in the preceding two weeks, rose again to 454 last week. These included 187 from measles, 104 from whooping-cough, 55 from diarrhœa, 34 from "fever" (principally enteric), 25 from diphtheria, 25 from scarlet fever, and 24 from small-pox. No death from any of these zymotic diseases was registered last week in Derby; while they caused the highest death-rates in Liverpool, Blackburn, Cardiff, and Newcastle-upon-Tyne. The greatest mortality from measles occurred last week in Salford, Liverpool, Birkenhead, and Newcastle-upon-Tyne; whooping-cough in Cardiff, Plymouth, and Blackburn; scarlet fever in Preston and Wolverhampton; and "fever" in Norwich, Portsmouth, and Cardiff. The 25 deaths from diphtheria in the twenty-eight towns included 16 in London, 3 in Liverpool, 2 in Sunderland, and 2 in Cardiff. Small-pox caused 32 deaths in London and its outer ring of suburban districts (exclusive of 16 deaths of London residents recorded in the metropolitan asylum hospitals and camp at Darenth), 2 in Hull, and 1 in Manchester. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1389, 1201, and 1222 on the three preceding Saturdays, had declined to 1119 at the end of last week; the admissions, which had been 272, 180, and 197 in the previous three weeks, declined to 163 last week. The Highgate Small-pox Hospital contained 62 patients on Saturday last, 13 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined from 305 to 231 in the preceding four weeks, further fell last week to 196, and were 46 below the corrected weekly average. The causes of 82, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Blackburn, Bolton, and in five other smaller towns. The largest proportions of uncertified deaths occurred in Huddersfield, Sunderland, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·8 and 20·6 per 1000 in the preceding two weeks, was 20·8 in the week ending June 20th, and exceeded by 2·5 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·6 and 18·5 in Aberdeen and Paisley, to 22·8 in Glasgow and 28·9 in Greenock. The 508 deaths in the eight towns included 17 which were referred to measles, 16 to whooping-cough, 12 to diarrhœa, 10 to "fever" (typhus, enteric, or simple), 6 to scarlet fever, 2 to diphtheria, and 1 to small-pox; in all 64 deaths resulted from these principal zymotic diseases, against 74 and 63 in the preceding two weeks. These 64 deaths were equal to an annual rate of 2·6 per 1000, which was 0·1 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 15 and 13 in the previous two weeks, rose to 17 last week, of which 9 occurred in Glasgow, 4 in Greenock, and 3 in Edinburgh. The 16 deaths from whooping-cough showed a further decline from recent weekly numbers, and included 9 in Glasgow, 3 in Greenock, and 2 in Edinburgh. The 12 deaths attributed to diarrhœa showed a decline of one from those in the previous week, and were 8 below the number in the corresponding week of last year. The deaths referred to "fever," which had been but 3 and 7 in the previous two weeks, further rose to 10 last week, of which 5 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. Five of the 6 deaths from scarlet fever were returned in Glasgow. The fatal case of small-pox also occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126 and 94 in the preceding two weeks, were again 94 last week, which, however, exceeded by 4 the number returned in the corresponding week of last year. The causes of 82, or more than 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 23·1 and 29·1 per 1000 in the preceding two weeks, declined again to 27·5 in the week ending the 20th inst. During the first eleven weeks of the current quarter the death-rate in the city averaged, however, no less than 30·3 per 1000, the rate during the same period not exceeding 19·8 in London and 18·5 in Edinburgh. The 186 deaths in Dublin last week showed a decline of 11 from the number in the previous week, and included 20 which were referred to the principal zymotic diseases, against 15 and 24 in the preceding two weeks; 6 resulted from measles, 4 from scarlet fever, 3 from whooping-cough, 3 from diarrhœa, 2 from fever, 1 from diphtheria, and 1 from small-pox. These 20 deaths were equal to an annual rate of 3·0 per 1000, the rate from the same diseases being 2·7 in London and 1·9 in Edinburgh. The fatal cases of measles, which had been 13, 9, and 11 in the previous three weeks, declined to 6 last week, and were fewer than in any week since the middle of February last. The 2 deaths from "fever" were 5 below the number in the previous week, while those from scarlet fever, whooping-cough, and diarrhœa showed an increase. The fatal case of small-pox was the first recorded within the city since the beginning of the year. Seven inquest cases and 7 deaths from violence were registered, and 50 deaths were recorded in public institutions. The deaths of infants were 11 fewer than the number in the previous week, while those of elderly persons had increased. The causes of 31, or nearly 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

AMONG the officers who left Egypt for England, invalided, by the *Oregon*, on the 23rd inst., were Surgeon-Major F. Ferguson, Surgeon-Major P. R. Gabbett, and Surgeon K. S. Wallis. Surgeon W. Turner left Suakin, invalided, on the 16th inst., per *Lochard*.

The hospital ship *Ganges* has left Portsmouth for Suakin, where she will embark additional invalids for England. With the exception of a medical staff, consisting of forty-six doctors, nurses, and others, she went out empty.

ARMY MEDICAL STAFF.—Brigade Surgeon Nathaniel Norris is granted retired pay, with the honorary rank of Deputy Surgeon-General.

INDIA OFFICE.—The Queen has approved of the retire- from the Service of the following officers of Her Majesty's Indian Military Forces:—Surgeon-General William Robert Cornish, C.I.E., of the Madras Army; Brigade-Surgeon Sarkies Michael Shircore, of the Bengal Army. The following officers are granted a step of honorary rank on retirement:—Deputy Surgeon-General William Pearl, of the Madras Army, to be Surgeon-General; Brigade Surgeon William Henry Kirton, and Brigade Surgeon John Jones, M.D., of the Bengal Army, to be Deputy Surgeon-Generals.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon John Cockburn Messer, M.D., has been placed on the Retired List, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets.

The following appointments have been made:—Staff Surgeon Herbert M. Nash, to the *Thunderer*; Surgeon Harold R. Osborne, to the *Philomel*; Surgeon Myles O'C. M'Swiny, to the *Valiant*; Joseph Stephens, M.D., to be Surgeon and Agent at Brighton and Blackrock: J. H. Foley, to be Surgeon and Agent at Carnsore and Rosslare; and Edward Greeve, M.D., to be Surgeon and Agent at Bonmahon.

ARTILLERY VOLUNTEERS.—1st Cornwall (Duke of Cornwall's): Arthur Hodge, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—3rd Hampshire: Edward Thomas Crouch, Gent., to be Acting Surgeon.—1st Cheshire: Francis Peirce, Gent., M.D., to be Acting Surgeon.—1st Perthshire: Alexander Thom, jun., Gent., M.D., to be Acting Surgeon.

UNIVERSITIES OF EDINBURGH AND ST. ANDREWS PARLIAMENTARY REPRESENTATION.—A dinner has, we understand, been arranged to take place at the Holborn Restaurant on Friday, July 3rd, at 6.30 P.M., for the purpose of giving Conservative electors of the Universities of Edinburgh and St. Andrews an opportunity of meeting Mr. J. H. A. Macdonald, Q.C., LL.D., Dean of Faculty, and Lord Advocate for Scotland under the new Ministry, the Conservative candidate for the representation of these universities in Parliament at the next election. Mr. Æneas Mackay, advocate, Edinburgh, is spoken of as the Liberal candidate for the seat. It is greatly to be regretted that a member of our own profession does not aspire to the representation of this important constituency.

Correspondence.

"Audi alteram partem."

THE DETERMINING TENDON IN DORSAL DISLOCATIONS OF THE HIP.

To the Editor of THE LANCET.

SIR,—We have been in the habit in this country—and it is an error into which I believe all our text-books lead us—of conceding to Professor Bigelow the honour of pointing out the influence of the obturator internus tendon in separating the dislocation upwards and backwards on to the dorsum ilii from the dislocation backwards, or upwards and backwards, into the sciatic notch, for which cumbersome nomenclature I propose in future to adopt the terms *superiliac* and *supersciatic.* Without doubt, we are much indebted to Professor Bigelow for his admirable work published in 1869, which has done so much to awaken a new interest in dislocations of the hip; but very difficult is it to know all that distinguished authors have written before our time, and Bigelow has clearly overlooked Malgaigne's *observations.* There is room in the world for all great men, and I am sure Professor Bigelow will owe me no ill-feeling for pointing out that the distinguished French surgeon, J. F. Malgaigne, had long forestalled his observations on the influence of the obturator tendon. Indeed, considering the emphasis with which Malgaigne insists on this point, it is curious that it should not have attracted the notice of subsequent readers and writers. I will transcribe Malgaigne's words as they appear on p. 837 of his work "Traité des Fractures et des Dislocations," tome ii., published in 1855:—

"Ce qu'il faut faire ressortir, c'est que, dans cette luxation, *la tête s'échappe toujours au-dessous de l'obturateur interne* qui occupe la petite échancrure sciatique, et des jumeaux qui sont en quelque façon ses satellites. Tantôt elle déchire seulement le carré qui est au dessous, tantôt seulement les jumeaux, tantôt les jumeaux et le carré à la fois, *l'obturateur interne restant comme une barrière pour empêcher la tête de remonter;* et enfin, dans le cas de Wormald, si l'obturateur était rompu, ce qui restait des jumeaux en faisait l'office. *Sans doute cette barrière peut être franchie, et alors la luxation devient iliaque;* mais quand elle est primitivement iliaque, c'est-à-dire quand la tête est sortie au-dessus du muscle obturateur interne, je doute qu'elle puisse redescendre au niveau de l'épine sciatique, à moins qu'elle n'y soit ramenée par les manœuvres du chirurgien. En un mot, *la tête sortant par-dessous l'obturateur interne est toujours luxée sur l'ischion,* et peut consécutivement remonter sur l'ilium; *la tête sortant par-dessus donne toujours une luxation iliaque.*"

The italics are my own, but nothing can be clearer or more emphatic than this statement of the influence of the tendon of the obturator internus in separating the supersciatic dislocation from the superiliac.

I am, Sir, yours truly,
R. CLEMENT LUCAS, B.S. Lond., F.R.C.S.

Finsbury-square, June, 1885.

"RENAL" PULSE ASSOCIATED WITH CHEYNE-STOKES' RESPIRATION.

To the Editor of THE LANCET.

SIR,—Professor M. Foster has been kind enough to afford me an explanation of the following observation made and inserted by me in my notes on a case of Dr. Whipham's in the York ward of this hospital. The professor was also kind enough to consider the observation sufficiently interesting for me to submit it to you for publication in THE LANCET.

"*Case of William S——, York ward, St. George's Hospital, May 28th,* 1885.— ...... The pulse at one moment is hard and full (renal), then it commences to slow down and grow weak, until, for a moment, it ceases entirely; again, after an instant's cessation, it recommences, growing slowly faster and stronger, until at the end of a few seconds it has become once more a pulse of the 'renal' type. Associated with this is the phenomenon known as 'Cheyne-Stokes' respiration.'"

But the most interesting part of the observation was, to use Professor Foster's own words, "that the heart and respiration alternated in rhythm, the heart being in full swing at pause of respiration, and being inhibited during height of respiratory period."

Professor Foster's explanation of this was that "apparently coincident with changes in the medulla oblongata leading to Cheyne-Stokes' respiration was a stimulation of the cardio-inhibitory centre in the medulla, occurring alternately with the former."

Being unaware that this state of the pulse has before been observed in conjunction with Cheyne-Stokes' respiration, I have ventured to submit this letter to you, in the hope that I may learn whether other observers besides myself have previously noted the fact. I may add, that on my calling attention to the above, it was observed in this case by others, and at the same time. Any excitement of the patient (he had been delirious for some days previous to, and was in a semi-comatose state at the time of, observation), such as moving him in his bed, &c., caused this double phenomenon to cease, only to return, however, when the patient was once again in his semi-comatose condition.

I am, Sir, yours faithfully,
HUGHES R. DAVIES,
Clinical Clerk to Dr. Whipham.

St. George's Hospital, June 17th, 1885.

THE COLLEGE ELECTION.

To the Editor of THE LANCET.

SIR,—Will you allow me to correct an important error in my letter which appeared in your impression of last week—an error which has just come to my knowledge, and which I am grateful for having had more accurate official information communicated to me, that now enables me at once to rectify it. I stated "that the office of Examiner in Surgery was restricted almost exclusively to members of the Council" of the College, whereas this is certainly not an absolute rule. As exceptions may be mentioned the present President and both the Vice-Presidents, each of whom was elected by the Council as an Examiner in Surgery before he became a member of Council, and the last two such Examiners elected are not on the Council.

I feel that I ought to have ascertained these facts, or have remembered the more recent exceptions, before making a statement which, however, had reference to the principle of generally combining the two offices of Examiner in Surgery and member of the Council.

Trusting you will insert this communication in your next impression, I am, Sir, yours obediently,

London, June 24th. FREDERICK JAMES GANT.

THE LATE MEDICAL OFFICER OF HEALTH FOR LEICESTER.

To the Editor of THE LANCET.

SIR,—My attention has been directed to your editorial note on the resignation of the medical officer of health for this borough, and I regret to find that you have been entirely misled by an article which recently appeared in a local paper. As a matter of fact, Dr. Johnston's resignation was due to the increase in his private practice preventing him giving that amount of time and attention to the duties of his office which his appointment required. This was assigned in his letter of resignation as the reason of his retirement, and in that letter he acknowledged the assistance he had ever received from the sanitary committee of this corporation. I feel it is due to my committee, to yourself, and to the medical profession generally—and I am pleased to say we have three members of the profession in the committee—that this explanation should be made; and its insertion will therefore oblige, Yours truly,

THOS. WINDLEY,

June 17th, 1885. Chairman of Sanitary Committee, Leicester.

CHESS. — Lord Tennyson and Mr. Ruskin, respectively president and vice-president of the British Chess Association, have, it is announced, each consented to give a copy of his works, with autograph, as prizes to be competed for in the tournament now proceeding. Lord Tennyson's prize is for the best two players in consultation, belonging to the professions of Medicine, the Law, Church, Army, or Navy.

MANCHESTER.

(*From our own Correspondent.*)

THE HOUSING OF THE POOR.

THE report issued by the Royal Commission on the housing of the poor is, to say the least of it, disappointing so far as suggesting any substantial remedy for the evils of overcrowding among the lower classes, the existence of which it emphatically demonstrates. In Manchester, some time ago, two experiments on a small scale were tried on a semi-philanthropic basis, but these have, up to the present, not been a financial success, though there is more prospect of this in the near future. The Town Council have not been inactive so far as demolishing whole districts in some of the worst neighbourhoods, but the failure has been in the lack of building houses in lieu of those destroyed, as the large vacant plots, especially in the neighbourhood of Deansgate, show. This subject is still occupying the attention of the municipal authorities; and in the last report of their medical officer of health allusion is made to this. He thinks that some attempt should be made to provide, outside the city, cottage dwellings to some considerable extent for the better-class artisans and operatives within a distance of two or three miles of the centre of the town, with tram and railway facilities for getting to and from their work. Probably some such arrangements as those on the Shaftesbury estate, near Battersea-park, London, might be found practicable, and he hopes that by thus removing the upper grades of the working class those lower in the scale would be able to use the cottages and houses set at liberty by others, and thus the lowest and worst class of property might more rapidly be got rid of. It is not unlikely that ere long some such scheme as this will be brought before the notice of the public generally and their help solicited, as it is admitted to be beyond the powers of the Corporation, even if they were willing to undertake the working out of such a scheme. There can be no doubt as to the benefit which would be derived by all concerned if such a project were carried out; those workmen and their families will benefit both physically and morally, whilst those remaining in the city would no longer be compelled to inhabit the slums and dens in which so many at present live.

THE SUPERVISION OF OUR MEAT-SUPPLY.

An interesting paper by Mr. Vacher was discussed at the last meeting of the Northern Association of Medical Officers of Health, the subject being the want of proper supervision of our meat-supply; he showed how very lax in many places are the regulations as to the proper control and arrangement of slaughter-houses and how easy it is for diseased animals to be put into the market as food. He advocated some such universal supervision and registration of all slaughter-houses and meat shops as now exist in regard to bakehouses and milk-shops and dairies, together with an official examination of all meat before being exposed for public sale.

THE COLLIERY EXPLOSION.

The columns of the daily papers will have informed your readers of the terrible catastrophe at Messrs. Knowles' colliery here last week. The scenes at the pit-mouth were heartrending in the extreme. It is known that moer than 170 lives have been lost. Within a very short time of the explosion a number of medical men were in attendance at the mine, but there was little to be done by them, as most of those who did not at once make good their escape were suffocated by the after-damp, or, as happened in many cases, sank half suffocated into the water which made its way into the workings, and were thus drowned. Some few of the injured who were got out alive were taken to the Children's Hospital, Pendlebury, and to the Salford Hospital. Surely, it does not seem too much to ask science that explosions such as this should be rendered almost impossible. If the ventilation were more vigorous, and the air swept through the workings with more force, escapes of inflammable gas might be so quickly diluted as to be rendered non-explosive. Great sympathy has been expressed throughout the land for the families of the sufferers, and the Lord Mayor of London has offered assistance. Our own mayor took immediate steps to open a relief fund, which has been promptly responded to, so that it is to be hoped that the sorrow and misery caused by this awful catastrophe will be to some little extent alleviated.

EXTENSION OF OWENS COLLEGE AND OF THE SALFORD AND THE EYE HOSPITALS.

The extensions of the Owens College are proceeding apace and the original block is now almost shut out of view from Oxford-road by the new wing. The College, like so many of the public buildings of Manchester, suffers architecturally by being so closely shut in on all sides that no good view of it as a whole is obtainable. The extensions, too, of the Salford Hospital are' progressing rapidly, and the new Eye Hospital is now practically complete, and will soon be ready for opening.

COUNTRY HOLIDAYS FOR POOR CHILDREN.

The committee who last summer so successfully organised country holidays for poor children of two or three weeks are again pursuing their good work in this direction, and ask for increased help, that many more of our children from the slums may this year, for a few weeks, breathe the purer air of the surrounding country villages.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE MEASLES IN NEWCASTLE.

THE epidemic of measles still prevails, and shows little sign of abatement as to numbers attacked; but I would fain hope, from conversation with practitioners, that the type is undergoing some change for the better as regards severity. The weather has not been at all favourable these last couple of weeks, considering the season, for any bronchial affections, but has been characterised by considerable variation of temperature, with high and gusty winds; upon the whole the temperature has been low for midsummer, with an absence of bright sunshine. As usual, when we are troubled with any general illness our papers are crowded with letters and suggestions from writers who, no doubt with the best intentions, know very little about what they are writing. One writer to-day commences very well with good general directions as to isolation, certification, and disinfection, &c., then he makes the utopian suggestion that a policeman or sanitary officer should be stationed day and night before each infected dwelling to insist upon the production of a pass or permit from the medical officer of health from every person leaving the infected house. Medical men are to wear waterproofs on visiting each patient, these garments to be supplied at the cost of the town by the sanitary authorities.

FATAL ACCIDENT TO A SURGEON.

A shocking and fatal accident occurred to Mr. John Middleton, of Butterknowle, near Bishop Auckland. About nine o'clock on the night of the 15th, as he was riding home to Butterknowle from Woodlands, his horse stumbled and fell, throwing its rider with such force to the ground that on being picked up he was found to be unconscious, and to have sustained a fracture of the skull which caused death in sixteen hours. Mr. Middleton, who was in his thirty-second year, was a L.R.C.S., and belonged to a well-known family in Ireland, being a son of the late Dr. Middleton of Mullingar. Much sympathy is felt for his widow. The funeral was attended by crowds of friends and patients.

Newcastle-on-Tyne, June 23rd.

EDINBURGH.

(*From our own Correspondent.*)

EDINBURGH FEVER HOSPITAL.

THE rather anomalous system of charitable support by which the Edinburgh Fever Hospital has been maintained for some years will come to an end on July 1st, after which date the necessary funds will be provided from the burgh rates. It is nearly a year since Lord Shand, one of the directorate, drew the attention of the managers of the Royal Infirmary to the fact that they were supporting an institution the maintenance of which was by statute incumbent upon the Town Council. The managers subsequently passed a resolution not to provide for the support of the Fever Hospital after the end of this month; and at a meeting held on the 22nd inst., they decided to offer the present buildings to the Town Council for a sum of £4000. These buildings are a part of the old infirmary, formerly known as the "Surgical House." They have been of late completely renovated; and as they, with the valuable site they occupy, are worth fully twice the sum named, it is scarcely possible that the civic authorities will decline the generous offer made to them.

GENERAL MEDICAL COUNCIL COMMISSIONERS.

The commissioners appointed by the General Medical Council to inquire into the system of teaching and examinations in the Scottish medical schools are at present in Edinburgh. They are attending the final examinations for the degree of M.B. and C.M. in the University, which are just now being held.

MOVEMENT OF THE ULNA IN PRONATION.

At the meeting of the Medico-Chirurgical Society held last week, Mr. C. W. Cathcart gave a demonstration of his views upon the causation of the lateral movement of the ulna which occurs in pronation. As the result of a series of experiments, he concludes that this movement is due to a rotation outwards of the humerus, which accompanies pronation, and which causes the inner condyle and the ulna to pass in a forward and outward direction. After demonstrating that the apparent lateral movement of the ulna does exist, he proceeded to show that it does not occur when the humerus is absolutely fixed; and to demonstrate this satisfactorily he made use of a case of complete ankylosis of the shoulder-joint, where any movement of the humerus was at once registered by corresponding movements of the scapula. When the whole of the shoulder girdle and the humerus were fixed, it was found that the lateral movement of the ulna did not occur, and it was hence concluded to depend upon the mobility of the humerus.

REMOVAL OF UPPER EXTREMITY.

Mr. Joseph Bell showed at the same meeting a patient whose whole upper extremity he had removed for sarcoma of the scapula. The recovery was a good one, and the general health had much improved since the operation.

Edinburgh, June 23rd.

PARIS.

(*From our Paris Correspondent.*)

CÆSAREAN SECTION.

At the meeting of the Academy of Medicine last week Dr. Guéniot read his report on a work forwarded by Dr. Closmadeuc relative to the Cæsarean section. The author had performed the operation three times successfully as regards the mother, and twice with equal success as regards the child. These operations were performed in the country under circumstances comparatively unfavourable, and if the patients got well it was, in Dr. Guéniot's opinion, owing to the mildness of the weather (month of May) which permitted the room occupied by the patients to be thoroughly ventilated, to their robust constitution, and finally to the ability of the operator. Encouraged by the successful issue of these cases, Dr. Closmadeuc is disposed to rehabilitate the Cæsarean section in opposition to Porro's operation—that is to say, the complete ablation of the uterus, which tends to grow in favour at the present time. On this Dr. Guéniot remarked that without going so far as Dr. Closmadeuc, he would affirm that Porro's operation is not so devoid of danger as one would be led to suppose, as the mortality from it has been registered at 58 per cent. Moreover, the Cæsarean section, performed with all the modern improvements which have been made in abdominal surgery, is not attended with the same danger as formerly.

A NEW APPARATUS FOR THE ADMINISTRATION OF CHLOROFORM.

In reference to his experiments on the production of anæsthesia with a mixture of chloroform and atmospheric air, M. Paul Bert presented, at the last meeting of the Academy of Sciences, a very ingenious and convenient apparatus, invented by M. Raphael Dubois, by which the quantity of chloroform and air may be regulated at will. The apparatus is reported to have been employed in a great number of operations in France and Belgium. M. Bert states that, if the patient be not addicted to spirits, he should have a mixture containing ten grammes of chloroform to a hundred litres of air, and seven or eight minutes suffice to obtain anæsthesia; whereas an alcoholic subject would require ten to twelve minutes. As soon as sleep is obtained, by a special arrangement of the apparatus the strength of the mixture is reduced to six grammes to the hundred litres, which is sufficient to maintain the anæsthesia. In conclusion, M. Paul Bert brought to notice the successful results obtained by a Belgian surgeon in five operations under this method—two tracheotomies and three ovariotomies.

LIMITATION OF THERMAL TREATMENT AT AIX-LES-BAINS.

A ministerial decree lately published in the official journal has caused some discontent, and justly so, among the medical men of Aix-les-Bains, as the decree limits to twenty-one days the maximum duration of the thermal treatment accorded gratuitously to certain privileged persons. The medical men have protested against the officious and unwarrantable interference of the Minister of Commerce, from whom the decree emanated, concerning their professional duties. The protest has had the support of the municipal authorities and the Deputy of Savoy, the latter having personally addressed the Minister on the subject, and it is hoped that this functionary will see his error and annul the decree without delay.

OUTRAGES BY LUNATICS.

There is evidently some mismanagement in the lunatic asylums of this country, for within the last two or three weeks circumstances have occurred among the inmates that would justify this assertion. About a week ago a lunatic, in the Saint Pierre Asylum at Marseilles, who was suddenly seized with hallucination, rushed out of his bed at night and, attacking another inmate with a saucepan, struck him a severe blow on the head, causing instantaneous death. Only a few days previously another sad occurrence took place in the same asylum. A keeper put two patients in separate baths and left them for a short time. During his absence one of them got out of his bath and turned on the tap of hot water into the bath of the other. When the keeper returned he found the unfortunate creature scalded to death. Last week another tragic scene took place in the lunatic asylum at Lehon, near Dinan, which is under the management of the Brothers of Saint Jean de Dieu. In this case one of the lunatics attacked a brother and struck him on the head with his wooden shoe, causing death after twelve hours of suffering. Another brother who had come to his assistance was severely bruised on the face by another madman, also with his wooden shoe. Both the patients got very much excited and made off for the doctor's residence with the intention of killing him, but, fortunately, they were prevented. The patient who murdered the brother had strangled his wife and attempted to kill his aunt, on which account he was sent to the asylum. Since his detention, however, which commenced some years ago, he appeared to be very quiet, and was considered almost cured.

Paris, June 23rd.

Obituary.

THOMAS PRETIOUS HESLOP, M.D., F.R.C.P.

ANGINA PECTORIS, the fatal ending of John Hunter Charles Bell, and many other illustrious lives, was the cause of Dr. T. P. Heslop's death at Braemar on the 17th inst. The son of a Scotch officer in the Artillery and of an Irish lady, Dr. Heslop was born in the West Indies in 1823. His boyhood was passed under the roof of his uncle, Dr. Thomas Underhill, the leading practitioner at Tipton, Staffordshire. Here was imbibed and cultivated a love for medical study, afterwards pursued with conspicuous success in Dublin, and in Edinburgh, where he graduated M.D. in 1848. A few months later, the governors of the Birmingham General Hospital resolved on dividing the work of their hitherto single resident officer, and Dr. Heslop was elected the first house-physician of that institution. It was not long before he gave evidence of that ardour of temperament which characterised him through life. The new appointment was soon vacated; but the young physician had already given such striking proof of uncommon aptitudes that he was not long out of office. Successively Professor of Physiology in the Queen's College, and physician to the Queen's Hospital and the General Dispensary, he became the leader of the staff of the Children's Hospital, which he founded, as he did the Skin and Lock Hospital. He also contributed powerfully to the establishment of the Women's Hospital and of the Birmingham Medical Institute. He was a justice of the peace, a governor of King Edward's School, and a trustee of Sir Josiah Mason's Science College. Of the latter institution he was bailiff and President of Council at the time of his death; and he could not have left a more worthy and appropriate monument than the library of the College, which owes its chief treasures to his best impulses. Inspired by many noble sentiments, impelled by tumultuous energy, faithful to his life's work, without heeding the unerring warnings of anginal seizures, Dr. Heslop's was a great life. Poor in worldly means, like many other distinguished men, at the onset of his career, his rise to comparative affluence as a consulting physician was not rapid. When he realised it, unlike some successful men, he was most generous in the partition of his share of fortune's favours. He was unmarried; and so intense was his devotion to the institutions with which he was officially connected, that, for them, his loss is wellnigh irreparable.

D. MANSON FRASER, M.A., M.D.

DR. FRASER, whose untimely death in Borneo we recorded in our last issue, was born at Invergordon in 1857, and was educated at the Grammar School and University of Aberdeen. At the latter place he had a distinguished career, graduating as M.A. in 1876, with first-class honours in Mathematics and Natural Philosophy, and honours in Natural Science, besides being Boxhill Mathematical and Natural Science prizeman. He immediately followed on to medicine, and graduated M.B., C.M., with honours and thesis commended, in 1879. He received the degree of M.D. in 1881. In 1878-79 he was house-physician at Aberdeen Royal Infirmary; in 1879-80 he held a similar appointment in the Northern Hospital, Liverpool; and thereafter, for three years, was a medical officer under the Metropolitan Asylums Board, London, being chiefly engaged at the fever and small-pox hospitals of Homerton, Newcross, ship *Atlas*, and Hampstead. In September, 1883, he went out to Borneo as medical officer to the British North Borneo Company. Dr. Fraser was the author of numerous papers on medical and sanitary subjects, including one on the "State of the Prisons of England, and their Influence on the Diffusion of Small-pox among the English Population in the Eighteenth Century." For this paper he was awarded the Howard medal of 1882 from the London Statistical Society.

ROBERT RATTRAY, M.D., M.R.C.S.

THE death is recorded, at the advanced age of seventy-five, of Dr. Robert G. Rattray, late apothecary and medical superintendent of the Aberdeen Royal Infirmary. Dr. Rattray, who was a native of Aberdeen, went through the course of medical study common at the time in connexion with the university of that city. In 1831 he obtained the diploma of membership of the Royal College of Surgeons of England, and in 1845 took the degree of M.D. at Aberdeen University, being some years subsequently appointed lecturer in Materia Medica in King's College, Aberdeen. He received his appointment as apothecary in connexion with the hospital in 1840, having acted for some time previously as electrician; and in 1849 he was appointed resident medical superintendent, an office which he continued to fill till his retirement, on account of advancing years, in January, 1882, an allowance of £200 a year being then granted him in consideration of his long and faithful service.

CONSIDERABLE regret has been felt in Sheffield among Dr. Banham's medical *confrères* at his departure from that town. He goes to Reading, where he has received appointment as physician to the Royal Berkshire Hospital. This regret found expression in a dinner, which was held on Wednesday, June 17th, and was attended by many of his late colleagues at the Infirmary, Medical School, and Medico-Chirurgical Society, in addition to others from Sheffield and the neighbourhood.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone all the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board of Examiners on the 24th inst.:—

Bardet, Paul Charles Albert, Geneva.
Campion, George Goring, Manchester.
England, Walter Joseph, Southhill-park, *Hampstead.*
Gabriel, William Maurice, Gloucester-gardens.
Goffe, Frank Hampton, Birmingham.
Jones, Alexander John, Maida Vale.
Mackrell, Alfred Sextus, Queen Anne-street.
Mugford, George Henry, Exeter.
Peall, Frederick Snell, Brixton-rise.
Robinson, Arthur Bernard, Liverpool.
Smith, Charles Robert, Leamington.
Williams, Hugh Lloyd, Llanberis, N. Wales.

(Candidates referred, 4.)

UNIVERSITY OF OXFORD.—At a congregation held on the 18th inst. the following degrees were conferred:—

DOCTOR OF MEDICINE.—J. Price, Queen's.

BACHELOR OF MEDICINE.—F. Phillips, Balliol; R. Ward, Exeter; G. Buckmaster, Magdalen; A. Garrod, A. Greswell, A. Orr, Christchurch; L. Guilding, Worcester.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 17th inst. the following degrees were conferred:—

BACHELOR OF MEDICINE.—Samuel Herbert Habershon and Thomas George Styan, Trinity; Patrick Cumin Scott, St. John's; Thomas Ernest Hillier and Frederick Charles Wallis, Gonville and Caius; Sidney Morton Pearson Roberts, Christ's; Edward Waymouth Reid, Cavendish.

BACHELOR OF SURGERY.—Frederick Charles Wallis, Gonville and Caius; Sidney Morton Pearson Roberts, Christ's.

UNIVERSITY OF DURHAM.—At the recent examinations for degrees in Medicine and Surgery the following satisfied the Examiners:—

DOCTOR IN MEDICINE, FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Batchelor, Ferdinand Campion, M.R.C.L., L.R.C.P., L.S.A.
Harris, John Badcock, M.R.C.S., L.R.C.P.
Morris, John Edward, M.R.C.S., L.S.A.
Palmer, F. Stephen, M.R.C.S., L.R.C.P., L.S.A.
Ransford, Gifford, M.R.C.S., L.R.C.P.
Simpson, Reginald Palgrave, M.R.C.S., L.S.A.

DOCTOR IN MEDICINE (Essay).

Eastes, Frederick, M.B., M.R.C.S.
Prowde, Edwin Longstaff, M.B.
Pruen, Septimus Tristram, M.B., M.R.C.S.

MASTER IN SURGERY.

Aslett, G. Stratton, M.R.C.S., L.S.A.
Caleb, Clement Cornelius, M.B., M.R.C.S.
Roberts, James Reid, M.R.C.S., L.R.C.P.
Walker, Charles Pope, M.R.C.S.

BACHELOR IN MEDICINE (Second Examination).

SECOND CLASS HONOURS (in order of merit).

Roberts, James Reid, M.R.C.S., L.R.C.P.
Evers, C. John, M.R.C.S., L.S.A.
Maynard, Frederic Pinsent.
Richardson, James Nowell, M.R.C.S.

PASS LIST (in alphabetical order).

Aslett, G. S., M.R.C.S., L.S.A.
Aubrey, Alfred Reuben.
Boobbyer, P., M.R.C.S., L.S.A.
Bowden, Reginald Treacher, M.R.C.S., L.S.A.
Hall, George Rome.
Hillstead, Herbert J., M.R.C.S., L.S.A.
Hubbard, A. J., M.R.C.S., L.R.C.P.
Jones, John Lloyd Thomas.
Mead, Francis Henry.
Moore, Walter Francis, M.R.C.S.
Palmer, Sydney Joseph, M.R.C.S.
Plummer, H. Beddoes Wetherell.
Proud, Frederick.
Saw, Francis Albert.
Tabor, Charles James.
Walker, Charles Pope, M.R.C.S.

COLLEGE OF PHYSICIANS IN IRELAND.—At the June examinations the undermentioned gentlemen obtained the Licences in Medicine and Midwifery of this College*:—

MEDICINE.—W. E. Dawson, C. Faulkner, G. B. Flanagan, J. H. Foley, F. S. Grimshaw, E. Lambkin, B. Lane, A. J. Luther, J. Norton, D. M. O'Callaghan, M. P. O'Donovan, C. Penott, R. C. Thacker.

MIDWIFERY.—J. Bannon, G. Clarke, J. Moore, S. J. Morr, W. R. Parker, W. Rankin, W. E. Dawson, B. Lane, A. Luther, J. Norton, R. C. Thacker.

* The list given in our last issue was in some respects incomplete.

The following gentleman was admitted a Member:—

Henry Ivers Kirkpatrick.

The undermentioned obtained the Licence of the College at a special examination held on the 23rd inst:—

James Chambers.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentleman was admitted a Fellow on the 19th inst:—

G. B. White, A.B.

The Council has elected Mr. S. Webb an additional Examiner in Physics, Chemistry, and Medical Jurisprudence.

Society of Apothecaries.—The following gentlemen ssed their examination in the Science and Practice of Medine, and received certificates to practise, on the 18th inst.:—

Cones, J. Archibald, M.R.C.S., St. Bartholomew's Hospital.
Randell, Reginald Maurice Henry, M.R.C.S., Guy's Hospital.

n the same day the following gentlemen passed their amination in the Science and Practice of Medicine, rgery, and Midwifery, and received certificates to practise:

Bollen, Frederick St. John, St. Thomas's Hospital.
Warren, Sydney, St. Thomas's Hospital.

Dr. Joseph Smyth has been elected coroner for orth Kildare.

St. Mary's Hospital.—At a festival dinner in aid f the funds of this charity, which was held on the 24th st., subscriptions amounting to £2200 were announced.

During the week ending the 13th inst. seven aths were registered in Dublin from cerebro-spinal eningitis.

Poisoning by Laudanum.—The Hon. Mrs. Blake, who was on a visit to Viscount Monck, died last week from n overdose of laudanum.

Metropolitan Free Hospital.—The anniversary estival of this hospital was held on the 24th inst., when bscriptions to the amount of £3365 were obtained.

The Austrian Government, it seems, has refused to thorise the establishment of private cremation societies, n the ground that they might encourage crime.

Vaccination Grant.—Mr. John W. Hayward, of the Whitstable district of the Blean Union, has received the Government grant for successful vaccination (second time).

London Fever Hospital.—At a festival dinner in aid of the funds of this hospital, held on the 23rd inst., £517 were subscribed.

The Prince of Wales has accepted an invitation to visit Birmingham in the ensuing autumn, for the purpose of opening the Suburban Hospital, erected at Erdington by Mr. Jaffray of that town.

Bequests and Donations.—The Rev. William Irwin has left £947 to Jervis-street Hospital, Dublin.—The Belfast Royal Hospital has received £100 from Mrs. Esther McKinistry.

At Marlborough on the 20th inst., a man named Clark was remanded on the charge of attempting to poison, by means of oil of almonds, Dr. Burman, of Ramsbury, by whom he had been employed as groom and gardener, and by whom he had been threatened with dismissal.

The annual meeting of the Victoria (Philosophical) Institute took place on the 17th inst., at the house of the Society of Arts, when the address was delivered by Dr. J. Leslie Porter, President of Queen's College, Belfast, the subject being "Egypt, Historical and Geographical."

Earlswood Asylum for Idiots.—The annual report (which is printed by the inmates of the Asylum) has just been issued. During the year 642 patients have been cared for in the institution. The total receipts amounted to £33,643; and after payment of all expenses a sum of £2021 was transferred to the capital account.

Mr. Sydney Turner, coroner for the city of Gloucester, has intimated his intention of resigning his office, owing to his inability, by the Municipal Act of two years ago, to appoint a deputy to hold inquests on persons dying in the Gloucester Infirmary, of which institution Mr. Turner is an honorary surgeon.

Glasgow Obstetrical and Gynæcological Society. At a numerously attended meeting held in the Athenæum, Glasgow, on June 17th, this Society, which has been in process of formation for some time, adopted a provisional set of rules and elected the following office-bearers:—Honorary President: Professor Leishman, M.D. President: W. L. Reid, M.D. Vice-Presidents: Samuel Sloan, M.D.; Abraham Wallace, M.D. Treasurer: Robert Pollock, M.D. Secretary: J. Stuart Nairne, F.F.P.S. Council: G. Halket, M.D.; R. Park, M.D.; Murdoch Cameron, M.D.; J. Turner, M.D.; J. Marshall, M.D.

Presentation.—A very successful course of lectures, conducted by Dr. Rice Oxley, in the Institute, Lower Norwood, was recently brought to a close. The interest taken by the bodies of the district in the work of the class has been very encouraging, the attendance ranging from 140 to 150; and to show their appreciation of Dr. Oxley's lectures, they presented him with a handsome microscope.

Victoria Hospital for Children.—The foundation-stone of a building to serve as a nurses' home and out-patients' department at this institution was recently laid by the Princess Louise. From 1866 to last December there have been treated at the hospital 295,710 out-patients, and 6861 in-patients, of whom 1281 have been sent to the convalescent home at Margate, all being under sixteen years of age.

St. Marylebone General Dispensary.—At the centenary festival dinner of this institution, which was held recently, it was stated that during the past year medical relief had been given to upwards of 4400 persons; and that *in addition upwards of 2000 had availed themselves of a* provident asylum, whereby patients were admitted to the benefits of the dispensary on payment of one shilling per week.

The Pollution of the River Lea.—The special committee appointed by the parishioners of Hackney and Clapton, to consider the subject of the pollution of the Lea, have addressed a letter to the Lea Conservancy Board, in which they beg the Board to use its influence to hasten on the erection of the works already sanctioned by the Local Government Board, so as to secure as effectual a remedy as possible for the existing deplorable condition of the river.

Surgeon J. W. Daniel, of the Dorset Yeomanry, distinguished himself at the Military Tournament now being held at the Agricultural Hall, on the 24th inst., by taking the second prize in the lemon-cutting competition, value £15. Three times in succession he divided both lemons, a by no means easy feat, but at the fourth essay failed, being beaten by Riding-Master Browne, of the Commissariat and Transport Corps. Both received quite an ovation from the audience.

Queen's College, Cork.—The following prizes have been awarded in the Faculty of Medicine:—Practical Anatomy: 1st, J. W. Wolfe; 2nd, John Jackson; 3rd, P. P. Jennings. Certificate, J. V. Ryan. Chemistry: J. W. Wolfe. Zoology and Botany: J. W. Wolfe. The following prizes and certificates have been awarded in the classes of Practical Chemistry and Materia Medica, instead of those formerly awarded, which have been cancelled:—Practical Chemistry: 1st, W. J. O'Meara; 3rd, R. J. Duffin; 4th, E. R. Hennessy. Certificates of Honour: D. J. O'Mahony, M. J. O'Regan, and Francis John Perrott (equal). Materia Medica: 1st, R. J. Duffin; 2nd, Daniel O'Callaghan; 3rd, E. R. Hennesy. Certificate of Honour: John T. Walsh. The exhibition in Practical Midwifery has been obtained by Daniel Lane.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* The Lancet *before 9 o'clock on Thursday Morning at the latest.*

Aldridge, C., M.D., has been appointed Second Honorary Physician to the Plymouth Public Dispensary.

Bailey, William Henry, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon and Secretary to the Newark Hospital and Dispensary.

Clendinnen, Joseph George, L.R.C.S.I., L.A.H.Dub., has been appointed Medical Officer for the Third Sedgeley District of the Dudley Union, vice Gilbert.

Draper, Jas. William, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Almondbury District of the Huddersfield Union, vice Abbott.

Finegan, Arthur, L.K.Q.C.P.I., Assistant Medical Officer to the County Asylum, Morpeth, has been appointed Medical Superintendent of the County Mayo Asylum, Castlebar, Ireland.

Griffiths, Wm. Charles, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Llanwinio District of the Carmarthen Union.

Hern, William, M.R.C.S., L.D.S., has been appointed Assistant Dental Surgeon to the Dental Hospital of London.

Leigh, William Watkin, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Gellygaer Lower District of the Merthyr Tidfil Union, vice J. Leigh.

MILLER, WILLIAM FRANCIS, M.B., M.R.C.S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Health Officer for Carisbrook, Victoria.

MORRIS, CHARLES A., M.A., M.B., B.C.Cantab., M.R.C.S., has been appointed Resident Medical Officer to the Liverpool Royal Infirmary.

POTTER, J. H., M.R.C.P., M.R.C.S., has been appointed to act as Police Surgeon and Surgeon to the Coroner of Bombay, during the absence of Dr. Sidney Smith, on leave, or until further orders.

BOYDS, WM. A. S., L.R.C.P., M.R.C.S., L.S.A.Lond., has been appointed Surgeon to the Royal Berkshire Hospital, vice Moxhay, deceased.

STUDDERT, RICHARD CHARLES, M.D., B.Ch.Dub., has been reappointed *Medical Officer of Health for the Erith Urban Sanitary District.*

SWANSTON, CHARLES, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Government Medical Officer for the District of Mudgee, New South Wales.

Births, Marriages, and Deaths.

BIRTHS.

ALLEN.—On the 9th inst., at 41, Wellington-square, Hastings, the wife of Bryan Holme Allen, M.D., of a daughter.

CARTER.—On the 19th inst., at Saville House, Potter-Newton, Leeds, the wife of F. R. Carter, M.R.C.S., of a daughter.

CHILD.—On the 14th inst., at Vernham, New Malden and Coombe, the wife of Edwin Child, M.R.C.S., of a daughter.

HARRIS.—On the 11th inst., at Teignmouth, Devon, the wife of F. W. H. Davie Harris, Army Medical Staff, of a son.

HOAR.—On the 18th inst., at Maidstone, the wife of Charles Edward Hoar, M.D., of a son.

JOHNSTON.—On the 21st inst., at 2, Melbourne-street, Leicester, the wife of William Johnston, M.D., of a son (Frederic William Sinclair).

MACCULLOCH.—On the 19th inst., at The Touillets, Guernsey, the wife of W. Mansell MacCulloch, Esq., M.D., F.G.S., of a daughter.

PIGGOTT.—On the 21st inst., at Brookside, Clare, Suffolk, Frances Mary, wife of Edward A. Piggott, L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.Lond., of a daughter.

SANCTUARY.—On the 15th inst., at Castle-street, Salisbury, the wife of Thos. Sanctuary, M.D., of a daughter.

TURTLE.—On the 19th inst., at The Poplars, Gascoyne-road, South Hackney, the wife of James H. Turtle, M.D., of a son.

MARRIAGES.

BEAUMONT—VOULES.—On the 23rd inst., at All Saints, Margaret-street, London, by the father of the bride, W. M. Beaumont, Esq., M.R.C.S., *of St. James's-square, Bath, to Frances Elizabeth, daughter of the* Rev. F. P. Voules, Rector of Middle Chinnock, Somerset.

COTTELL—MURRAY.—On the 18th inst., at Crouch-hill, by the Rev. A. C. Murphy, D.Lit., Arthur Bowdich Cottell, Surgeon Medical Staff, to Helen Mackintosh, daughter of William M. Murray, Esq., of Brambledown. Indian, China, and Australian papers please copy.

SANGSTER—SHEPHARD.—On the 17th inst., at St. Mary's, Lambeth, by the Hon. and Rev. Canon Pelham, Rector, Charles Sangster, M.R.C.S., of 158, Lambeth-road, S.E., elder son of the late Martin Sangster, of Stockwell, to Elizabeth Jane, only daughter of Mark Shephard, of Roupell-park, Streatham.

SHADWELL — WHITTINGHAM. — On the 17th inst., at Walthamstow, St. Clair B. Shadwell, L.R.C.P.Lond., eldest son of J. B. Shadwell, Esq., I.C.S., of Cherrapoonjee, Bengal, to Marion Alice, second daughter of W. B. Whittingham, Esq., of North View, Walthamstow.

STOKES—HUNT.—On the 20th inst., at St. Pancras Church, Arthur Samuel Stokes, L.R.C.P., M.R.C.S., of Weldon, Northamptonshire, to Helen Matilda, daughter of Hutchinson Hunt, of Caldecott, Rutland.

VOGAN—LEATHERN.—On the 23rd inst., at the Parish Church, Bromley, Kent, James Norman Vogan, F.R.C.S., to Emma Jane, eldest daughter of Lewis Leathern, Esq.

DEATHS.

BENDALL.—*On the 18th inst., at Titchfield-terrace, Regent's-park, N.W.,* Howard Bendall, M.D., M.R.C.S., in his 32nd year.

BREDIN.—On the 23rd inst., at The Vines, Sutton Valence, Kent, Margaret Eliza, the beloved wife of John Noble Bredin, physician.

DANE.—On the 21st inst., suddenly, after a few hours' illness, at his residence, Finchley-road, South Hampstead, Thomas Dane, M.R.C.S., in his 52nd year.

HESLOP.—On the 17th inst., whilst travelling to Braemar, N.B., Thomas Pretious Heslop, M.D., F.R.C.P., of Birmingham.

OATES.—On the 19th inst., at Edinburgh, suddenly, Parkinson Oates, M.D., M.R.C.S., L.S.A.Lond., of Cambridge-street, S.W., and Lansdown-parade, Cheltenham, aged 67.

STACE.—On the 15th inst., at Abu Zatmeh, Soudan, of enteric fever, Arthur Frank Stace, Surgeon Army Medical Staff, grandson of the late Dr. Stace, of Southampton, aged 21.

WILSON.—At Cullen, Banffshire, James Wilson, F.F.P.S.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers t Correspondents.

All communications relating to the editorial business of th journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written o one side only of the paper.

Letters, whether intended for publication or private informa tion, must be authenticated by the names and addresses o their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs shoul be marked.

Letters relating to the publication, sale, and advertisin departments of THE LANCET *to be addressed "To th Publisher."*

THE TREATMENT OF DIPHTHERIA.

DR. ILLINGWORTH writes to complain that by the abstract of his lett on the treatment of diphtheria, which appeared in our last issue, h views are but imperfectly described. He points out that to say l recommends salicylate of soda and ammonia is but to state half of h prescription, for later on in his letter he advises the administration steel and chlorate of potash. In addition, he gave his reasons for pr scribing first the one and then the other, the insertion of which th crowded state of our columns prevented.

M.D.—It is not easy to foretell what view the Local Government Boa would take of the subject with all the facts before them; but probal their reply to both questions would be in the negative.

Anxious Inquirer may refer to THE LANCET of Dec. 27th, 1884, an Feb. 14th and 28th, 1885, for information on the point mentioned.

Dr. Malins (Birmingham).—A notice was already in type when our co respondent's communication arrived.

"THE TITLE OF 'DOCTOR' FOR LONDON MEDICAL STUDENTS."

To the Editor of THE LANCET.

SIR,—In reference to Mr. Wright's letter under the above heading i your last issue, will you kindly allow me to call your correspondent attention to the fact that the regulations of the University of Aberde require a professional curriculum extending over *four*, not six, years f the degree of M.B. and C.M.? If Mr. Wright spent the longer perio in obtaining his degrees, then it was his own fault, and he cannot us the fact as a valid argument. As far as regards the relative cost o living, fees, &c., I am convinced that for most English students a tw years' residence in Aberdeen in lieu of London would mean a con siderable saving, and not a "considerable extra expense."

I am, Sir, yours faithfully,
JAMES TURTON, M.R.C.S.
Brighton, June 22nd, 1885.

Dr. Mackey.—As the controversy is now closed, we think it would b inexpedient to print our correspondent's letter.

Dr. Sinclair (Dundee) will oblige by sending a copy of the pamphlet.

FLUSHING SEWERS WITH SEA-WATER.

To the Editor of THE LANCET.

SIR,—Will some of your readers interested in sanitary matters kind inform me if they have found any ill effects arise from partially flush the public sewers with sea-water? If so, what the ill effects were?

I am, Sir, yours faithfully,
M. O. H.
June 24th, 1885.

JEQUIRITY.

To the Editor of THE LANCET.

SIR,—Perhaps some of your readers would be kind enough to inform me through your columns of the result of treatment of [illegible] ulcer by jequirity, and if it has any power to check the spread of the disease.

I am, Sir, yours obediently,
A YOUNG PRACTITIONER.
June 22nd, 1885.

RESPIRATION IN COMPRESSED AIR.

[illegible] SUCHORSKY states (*Chem. Centr.* quoted in *Journ. Chem. Soc.*) that when compressed air is respired the absolute amount of oxygen inspired and of carbonic anhydride expired is diminished. The rhythm of the respiration remains unchanged. In all cases of mechanical hindrance (bronchitis), restriction of movement of the organs (pleuritis), or reduction of surface (pneumonia), the change of rhythm consists in a partial disappearance of the pause after expiration, and the times of inspiration and expiration become equal. Compressed air acts on the circulation in a twofold manner—on the one side it compresses all the capillaries of the outer surface and of the respiratory organs, causing a more complete emptying of the veins, and on the other side changes the distribution of blood in the system, causing an accumulation in the abdominal organs. The therapeutic action of compressed air may be referred exclusively to its mechanical action on the organism, and to the increase of partial oxygen pressure. The latter produces no perceptible effect on the oxidation process in the body; on the contrary, in pathological cases where respiration is impeded it tends to reduce the absolute amount of oxygen taken up and the carbonic anhydride expelled, as the organism obtains the necessary amount of air with less difficulty, and so the muscular work of the respiratory organs is economised. Consequently the therapeutical application of compressed air cannot be considered as facilitating oxidation and support of the body in sick cases, but as a saving of effort. Nevertheless, it would be erroneous to conclude that compressed air might in these cases be replaced by air rich in oxygen, since the compressed air exerts a series of favourable influences on the sick organism, and especially on the respiratory organs. The pressures employed varied between [illegible] and 1143 mm. of mercury.

J. W. D.—A notice of the death of the late Surgeon J. M. Young appeared in our impression of the 6th inst.

[illegible] E. E. P[illegible].—We cannot depart from our rule.

[illegible].—Messrs. Gallais and Co., Margaret-street, Regent-street.

OSMIC ACID IN NEURALGIA.

To the Editor of THE LANCET.

SIR,—In reference to the annotation in your issue of last week upon Dr. S[illegible]'s list of neuralgic cases treated by Neuber's method, may I be allowed to draw attention to an "ill effect," though slight, that was caused apparently by the osmic acid, in a case I attended about a month ago. The patient had a few weeks previously sprained a little finger, and complained when he consulted me of what he called "neuralgic pains" in the same. Having treated successfully a case of [illegible] two or three months' standing by the injection of a 1-per-cent. solution of osmic acid in *five-minim doses, repeated four or five times at* intervals of three days, I determined to pursue the same course with this one. I only used *four minims*, and in a few minutes the patient was [illegible] to find the pains had gone. The next morning, however, there was a painful and flushed swelling in the situation of the puncture—that is to say, between the extensor and abductor minimi digiti. This lasted for several days, and though the pain never returned in the finger a feeling of numbness in it was complained of, while the point of entrance of the needle smarted occasionally for two or three weeks. I should add that the finger did not belong to the "horny hand of [illegible] and its balance of circulation was probably on that account the more easily upset. Should the amount injected not be somewhat less than five minims in parts richly supplied with nerves? The injection was not repeated.—Yours faithfully,

WM. ASHTON ELLIS.
[illegible] Medical Officer, Western Dispensary, Westminster.
June [illegible], 1885.

HOME FOR EPILEPTICS.

To the Editor of THE LANCET.

SIR,—"M. G. E.," who is anxious to hear of an institution where a child subject to epilepsy will be well cared for, will be glad to hear of [illegible] Asylum, or School, near Maidstone. Let him write for prospectus to Mr. A'Vard. At present he has but a very limited number of boys, but a better place for weak-minded children there cannot well be. The house is *commodious*, the grounds are extensive, [illegible] the management is characterised by great liberality and kindness, and the terms are very moderate. A personal visit has convinced me that many parents with afflicted children would be glad to hear of such a home for them.

I am, Sir, yours faithfully,
[illegible] Heath, June 23rd, 1885. T. J.

A Parent should consult a qualified medical practitioner.

Dr. T[illegible].—The interesting paper will appear in an early number.

DR. TIBBITS MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—Will you allow me to acknowledge through THE LANCET, with many thanks, a donation of five guineas from J. Mitchell Clarke, Esq., for the benefit of the widow and family of the late Dr. Tibbits of [illegible]. Up to the present date the total amount received through THE LANCET is £[illegible] 5s.

I am, Sir, yours faithfully,
[illegible], June 23rd, 1885. JOHN APPLEYARD.

EXISTENCE OF WARTS AMONGST WORKERS IN CARBOLIC ACID.

To the Editor of THE LANCET.

SIR,—In the report of the meeting of the Academy of Medicine in Ireland (THE LANCET, June 6th, page 1037), I see that Dr. Ball, in his paper on cases of Cutaneous Epithelioma, mentions that "warts were numerous amongst the operatives who are employed in the manufacture *of carbolic acid*."

Last October, after some conversation with one of our travellers in Dublin, Dr. Ball wrote to me for information, to which I *replied as per enclosed* letter; and I am therefore much surprised that after the receipt of my letter such a statement should have been made. Further, I may say that our traveller, whom he saw and to whom he alludes, only worked a few months in the factory, and then was simply employed in our stores, where carbolic acid is neither made nor handled.

The occurrence of warts, even in a tar distillery, is probably not in any way due to handling the tar products, and I am informed by a large tar distiller in Manchester that warts are no more prevalent amongst his *workpeople* than amongst any other class of operatives.

I am, Sir, yours obediently,
Manchester, June 16th, 1885. R. LE NEVE FOSTER.

P.S.—I append an extract from a letter from the manager of the tar works in Dublin to whom Dr. Ball alludes:—"I beg to say, in reply to Dr. Ball's report in THE LANCET, that during the thirteen years that I am over these works only five cases of what Dr. Ball calls 'epithelioma' came under my notice, two of which we treated with caustic soda successfully, another was the man mentioned four years ago, one about six months ago (both these were treated by Dr. Ball), and the man who had the wart on his eyelid (under Dr. Storey's treatment), which latter case I am doubtful if it comes under this category. The man, eighty years of age, was employed at the neigbouring ammonia works, and not here. I believe if the men were a little cleaner, and washed themselves oftener, these cases would not occur. As you will probably conclude yourselves, we make not three, but six principal products—viz., crude naphtha, creasote oil, sublimed naphthaline, carbolic acid, anthracene, and, of course, pitch."

"Manchester, Oct. 8th, 1884.

"DEAR SIR,—In reply to yours of the 6th, our representative is labouring under some misapprehension, as during some nineteen years' connexion with the manufacture of carbolic acid I only know of two cases amongst our workpeople—and we employ over 100 hands—and both of them had warts before they came to us; they were brother and sister, and had previously worked at a blood albumen and catgut works respectively; the man only is in our employ, and the warts have gradually disappeared. The woman has left us some time, and I cannot say whether they improved or not whilst with us. Neither was attended by any medical man. With respect to our representative at Dublin, he was also afflicted with warts before he entered our employ, and as he has not had any inside connexion with the works for the past two years, I think his case can have little or no bearing on the matter.

"If there be anything further in which I can give you any help or information, I shall only be too glad to do so.

"Meanwhile I am, dear Sir, yours very truly,
"C. B. Ball, Esq., M.D., F.R.C.S." "R. LE NEVE FOSTER."

A Subscriber to THE LANCET *of Thirty-five Years.*—We do not think there would be any risk at the distance mentioned.

A REMARKABLE SUPERSTITION.

To the Editor of THE LANCET.

SIR,—In your issue of the 13th inst. there is a note on Hottentot pathology, in which it says that "the uterus is supposed after parturition to have a great tendency to fly upwards, and consequently after the second stage of labour the funis is carefully tied to one of the woman's toes." Now, it is curious that in this part of Ireland, within eight miles of Belfast, the lower orders have the same notion. In all cases when I happened to arrive after the birth of the child I found the funis tied to the woman's leg or thigh, "to prevent the after-birth going up about her heart." My own idea is that it has arisen from cases of post-partum hæmorrhage having taken place with retained placenta and the consequent feeling of fainting. It is remarkable how widespread is the idea. I am, Sir, yours faithfully,

GEORGE ST. GEORGE,
Lisburn, Ireland, June 17th, 1885. Surgeon, co. Antrim Infirmary.

CHAMPAGNE JELLY.

To the Editor of THE LANCET.

SIR,—During the illness of the late Lord Beaconsfield it was reported in the daily papers that he was much benefited by the use of champagne jelly—it being, in fact, the only nutriment he could take. Could any of your readers furnish the recipe for this, as I believe it might prove of service to a lady patient who during a somewhat protracted illness has tried nearly all the "triumphs" of the inventors of invalid foods, &c., and is "tired" of them all?—I am, Sir, your obedient servant,

June 23rd, 1885. PHYSICIAN.

A PRACTICAL SUGGESTION.

To the Editor of THE LANCET.

SIR,—As the General Medical Council seem somewhat perplexed as to what object they can legitimately apply their accumulated and increasing wealth, may I be permitted to suggest that they might very properly present every qualified medical man with a copy of their new Pharmacopœia—if only as a "small token of affection and esteem."

I am, Sir, your obedient servant,
French Hospital, W.C., June 16th, 1885. ALFRED S. GUBB.

Communications not noticed in our present number will receive attention in our next.

Communications, Letters, &c., have been received from — Dr. G. C. Roy, Sooree; Mr. C. E. LECTURES.

ANDERSON, Dr. McCALL:—
Clinical Lectures (Abstract of) on Intra-cranial Syphilis.
Lecture I., 1157

BARKER, Mr. A. E.:—
Clinical Lectures on Cases Illustrating Renal Surgery.
Lecture I., 95
Lecture II., 141

BRISTOWE, Dr. J. S.:—
Cavendish Lecture on *Hysteria* and *its* Counterfeit Presentment, 1059, 1113

BRUNTON, Dr. T. L.:—
Lettsomian Lectures (Abstract *of*) on *Disorders* of Digestion, their Consequences and Treatment.
Lecture I., 53
Lecture II., 141
Lecture III., 239

CLARK, Sir Andrew:—
Lumleian Lectures on some Points in the Natural History of Primitive Dry Pleurisies.
Lecture I., 519
Lecture II., 599
Lecture III., 649

COWELL, Mr. G.:—
Clinical Lecture on Two Cases of Injury from the Dynamite Explosion in Westminster Hall, 468

CROCKER, Dr. H. R.:—
Clinical Lectures on Scleroderma.
Lecture I., 191, 237
Lecture II., 927, 957

DALBY, Mr. W. B.:—
Lecture on Affections of the Throat and Nasal Passages associated with Disease of the Middle Ear.
Lecture III., 51.

DUCKWORTH, Dr. Dyce:—
Clinical Lecture on a Case of Disseminated Cerebro-spinal Sclerosis in an Early Stage, affecting exclusively the Right Extremities, 879

FENWICK, Dr. J.:—
Clinical Lectures on Cases of Difficult Diagnosis.
Lecture II., 1, 49

FINLAYSON, Dr. J.:—
Remarks on Laryngeal Paralysis and Inequality of the Pupils, as tending to Aid *and also* to Mislead in the Diagnosis of Thoracic Aneurysm, with some Observations on the State of the Pupil after Death and the Effect of Atropine, 3

GAIRDNER, Dr. W. T.:—
Clinical Remarks on a Case Illustrating Liability to Error in Diagnosis, 1025

GERVIS, Dr. H.:—
Annual Address delivered at the Obstetrical *Society of London*, 231

HARDIE, Mr. J.:—
Clinical Lecture on Congenital Tumours, 785

HUMPHRY, Professor:—
A Museum Lecture on the Anatomy of Spina Bifida, 357
The Annual Oration delivered on May 4th at the Medical Society of London on *Old* Age and the Changes incidental to it, 831

LEE, Dr. R. J.:—
Clinical Lecture on Malformations of the Heart, 371

MARSHALL, Mr. J.:—
Hunterian Oration delivered at the Royal *College of Surgeons of England*, 325

OSLER, Dr. W.:—
Gulstonian *Lectures* on Malignant Endocarditis.
Lecture I., 415
Lecture II., 519
Lecture III., 505

REYNOLDS, Dr. J. R.:—
Address to the Students of the Medical School and *University College*, Bristol, 1021

WEBER, Dr. H.:—
  Croonian Lectures on the Hygienic and Climatic Treatment of Chronic Pulmonary Phthisis.
    Lecture I., 484, 503
    Lecture II., 604
    Lecture III., 693, 737

Lee, Dr. R., on malformations of the heart, 371
——, Mr. A. B., the Microtomist's Vade-mecum (review), 893
——, Mr. H., on the radical cure of varicocele, 695
Leech, Mr. D. J., on sweet spirits of nitre, 597
Leeds, sanitation at, 631; General Infirmary, 545
Lees, Mr. A., on palatable predigested food, 647
Leeson, Dr. J. R., on cocaine as a local anæsthetic, 131
Lefroy, Canon, on the lunacy laws, 216
Legacies of 1884, the, 75
Legg, Dr. J. W., on the affinity of simple and malignant jaundice, 560; on Addison's disease, 1027
Leicester, the anti-vaccinationists at, 358, 377; health of, 914; the late medical officer of health for, 1096, 1183
Leipsic pathological chair, the, 78, 220
Leslie, Mr. W. M., on singular medical evidence, 1104
Lettsomian lectures, the, 260
Leucocythæmia, 755, 1086
Lewers, Mr. A. H., on spurious vaccination, 153
Lewes, health of, 679; lunacy case, the, 859
Lewis, Mr. W., on the application of midwifery forceps, 690
——, Surgeon C. B., the late, 171; obituary notice of, 318
Licking adhesive stamps and envelopes, 959
Life assurance offices and medical examinations, 737
Life-saving from drowning by self-inflation, 11
Lightning, deaths from, 414
Lincoln, the water-supply of, 358, 731; health of, 914
Ling, Dr. G., on cholera and its prevention, 677
Lister, Sir Joseph, 216
Litholapaxy, one hundred and eleven cases of, 375, 421, 467
Lithotomy, tobacco pipe mouthpiece forming the nucleus of the stone, 287; in the adult, cases of, 834, 930; renal, 800; supra-pubic, 1177
Lithotrity, use of cocaine in, 124; a case of, 704
Little, Dr. James Lawrence, death of, 768
Liver, atrophy of the, 662; clinical study of the, viewed through the urine, 700, 741; carcinoma of the, with great contraction of the stomach, necropsy, 747; primary carcinoma of, 844; infiltrating growth in, and adrenals of an infant, 231
Liverpool, isolation in Greater, 120; hospital for infectious diseases in, 167; proposal to rate hospitals in, 1050
Llanelly, health of, 636, 1055
Local Government Board, the report of the medical officer of, 35, 125; medical inspectors of, 304; medical and engineering inspectors at, 351
Locke, Mr. G., on pruritus vulvæ, 235
Locomotor ataxy, without disease of the posterior columns of the spinal cord, 430; with joint disease, 1038; hereditary, 353
London, open spaces in, 32; smoke, an apology for, 764; seasonal prevalence of continued fevers in, 993; the proposed new teaching university for, 86, 390, 575, 1134; the port of, 672
—— Fever Hospital, the, 33
—— Hospital, 1061
—— medical students, university degrees for, 677, 818, 852
——, University of, 25, 273, 351, 586, 861, 907, 1093; the M.D. examination at the, 132, 179, 714; convocation of, 267; the degree of B.Sc. of the, 1057; reform of the constitution of the, 1170; and the proposed teaching university, 390
Londoners, degeneration of, 369
Longstaff, Dr. G. B., on the seasonal prevalence of continued fevers in London, 993
Lord Mayor, the late, 718
Los Angeles for invalids, 321
Low, Mr. C., on the explosion at Shoeburyness, 157
Lower Thames Valley drainage, 643, 1109
Lowndes, Mr. F., on forensic medicine, 638
Lowson, Dr. D., on displacement and fracture of the axis, 221
Lozano, Dr. G. G., on the mortality of Madrid, 1165
Lucas, Dr. J., on the boats between Calais and Dover, 92; on cascara sagrada, 369, 502; on the Arabs wounded in the Soudan, 457
——, Mr. R. C., on fractures of the skull followed by collections of cerebro-spinal fluid beneath the scalp, 129; the determining tendon in dorsal dislocations of the hip, 1183
Lückes, Eva, Lectures on Nursing (review), 299
Lumbar colotomy, a case of, 932
Lumley, Mr. W. G., the Public Health Act, 1875 (review), 298
Lunacy Amendment Bill, the, 547, 626, 668, 806, 814
——, certificates in, 123; fees for, 924
——, deadlock in, 537
—— law reform, 42, 72, 118, 176, 257; and Poor-law medical officers, 267
—— laws at home and abroad, 573
Lunatics, imprisoned, 77, 355, 766, 810, 876; custody of, 862, 868; fractured ribs and scurvy in, 857; and workhouses, 1050
Lung, bullet wound of, 292; rupture of the, and probably of the liver, 661; destructive disease of, 749; obliteration of one, with displacement of the heart, 1048; and brain, sarcoma of, 844
—— diseases in wild animals, 341
Lungs, hernia of the, into the neck, 515
Lunn, Mr. J. R., on calculus and tumour of the bladder, 618; on osteitis deformans, 893; on a case of aneurysm of the abdominal aorta, 705
Lupton, Mr. H., on a case of intra-cranial hydatid, 802
Lupus, nature and treatment of, 254
Lush, Dr. W. J., on conscience money, 734
Lustgarten, Dr. S., on the bacillus of syphilis, 609
Lying-in hospital mortality, 534
Lymphadenosis, with multiple growths from the dura mater, 247

McArdle, Mr., on anomaly of the arch of the aorta, 754
Macaroni infection, 140
McAvoy, Dr. J., on glycerinum acidi carbolici in diabetes mellitus, 738
Macclesfield General Infirmary, 409
Macdonald, Mr., G. C., on a case of so-called catheter fever, 1164
McCulloch, Mr. T. C., on drinking paraffin oil, 972
McDonald, Mr. P. W., on two cases of single kidney, 979
McDonnell, Dr. C., presentation to, 184
——, Dr. R., on the nature and treatment of lupus, 254
Macdougall, Mr. A., on chronic chorea of forty-one years' duration; nerve-stretching for relief of pain, 742
McEwen, Dr. W., cases illustrative of cerebral surgery, 881, 934
Mackenzie, Dr. H., on a case of laryngeal and pulmonary tuberculosis, originating in simple chronic laryngitis, 256
M'Keown, Dr., on the prevention of ophthalmia neonatorum, 345
Maclagan, Dr. J., on Charcot's disease, 85
Maclean memorial, the, 269, 442
McLearn, Dr. J. O., on a case of chorea in a man aged fifty-six, 837
McLeod, Dr. K., on the prevalence of epidemic roseola in Calcutta, 383
McMunn, Mr. J., on the application of midwifery forceps, 457
Macpherson, Dr., on the use of ipecacuanha in dysentery, 476
"Mad doctors," worrying the, 954
—— dogs at large, 674
Madness, a magistrate's opinion on, 166
Madras, hospital for caste women in, 905
Magnetism, physiological effects of, 413
Maguire, Mr. W. R., on disinfecting chambers, 829

MEDICAL SOCIETIES.

ABERNETHIAN SOCIETY.—Sir James Paget on St. Bartholomew's Hospital and School fifty years ago, 1123

ACADEMY OF MEDICINE IN IRELAND.—Inaugural address; Melanotic sarcoma of the rectum, 56—Cardiac disease; Osteoma; Cancerous stricture in the sigmoid flexure of the rectum; Strangulation within a hernial sac; Removal of a hard calculus from the tonsils; Mammary tumour, 11—Three cases of ovariotomy, 209—Nature and treatment of lupus, 254—Congenital dislocation of the hip-joint; Cervical tumour; Bowel obstruction relieved by operation, 477—Transplantation of skin flaps without pedicle for the cure of cicatricial ectropia, 563—Inaugural address; Sewer gas and disease, 622—Gangrene of leg; Endocardial concretion; Tropical dysentery; Aneurysm at base of brain; Pericarditis in a horse; Anomaly of the arch of the aorta; Development of the azygos bloodvessels; An Andaman skeleton, 733—Operations for flat-foot; Removal of an ivory exostosis from the auditory meatus; Trichiasis, 848—Sloughing of the rectum; Acute pneumonia; Multiple exostoses; Cutaneous epithelioma, 1036—Treatment of uterine fibro-myomata, 1086—Complete excision of the clavicle for osteosarcoma and partial excision for necrosis, 1167

CAMBRIDGE MEDICAL SOCIETY.—Dislocation of hip; Myopia; Adenoid growths of the naso-pharynx, 209—Use of hyoscyamine in delirium tremens; Perineal section for cystitis in fractured spine, 346—Supposed cerebellar embolism; Fracture of pelvis with wound of artery, 478—Severe injury to head; Bullet wounds of skull; Sarcoma of ovaries, 993

CARDIFF MEDICAL SOCIETY.—The measles epidemic, 569.

CLINICAL SOCIETY.—Conclusion of the discussion on Charcot's disease, 11—Lesions of the frontal lobes; Recurrent hæmatemesis, with [illegible] a new method of using the œsophageal catheter, 295—President's address; Myxœdema; Sudden death in phlegmonous pharyngitis, 343—Locomotor ataxy without disease of the posterior columns of the spinal cord; Arrested rickets; Nephro-lithotomy, 430—Thrombosis of basilar artery; Insanity after ovariotomy; Colotomy with delayed opening of the bowel, 521—Treatment of spina bifida; Choreiform movements in infantile spasmodic paralysis; Carcinoma and calculus of the bladder; Pistol-shot wounds, 616—Amputation at hip-joint; Pityriasis circiné, 707—Sporadic cretinism; Inguinal aneurysm; Renal lithotomy, 799—Obstruction of arteries and veins extending over many years; Osteitis deformans; Hæmoptysis treated by artificial pneumothorax; Removal of calculus from vermiform appendix, 893—*Report on spina bifida*; Successful œsophagotomy; Raynaud's disease; Surgical treatment of tumour of the bladder, 989

EPIDEMIOLOGICAL SOCIETY.—Constitutional requirements for tropical climates, with special reference to temperaments, 159—Prevalence of epidemic roseola in Calcutta, 385—Prevention of heat apoplexy, 620—Seasonal prevalence of continued fevers in London; Plans of isolation hospitals, 993—Variola and the varioloid diseases of animals, 1036

HARVEIAN SOCIETY.—Presidential address, 252—Labour complicated by vaginal hernia; Purulent ophthalmia in infants; Effects upon the voice of operating for cleft palate; *Emphysema treated by the compressed air bath*; Early treatment of concomitant squint; Resection of the intestine, 620—*Apparatus for the transfusion of defibrinated blood*; Neglect of emetics in the treatment of disease, 661—*Ulcerative endocarditis*; *Hereditary* nature of hæmophilia, 801—Diagnosis of cervical stenosis; Use of the ophthalmoscope in medical practice, 992; Porro's operation; *Electrical diagnosis in nervous diseases*, 1036

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Fibroid tumour (sessile) in anterior wall of uterus; Hysterical ischuria; [illegible] transplantation; [illegible] nervous system; [illegible] poisoning; Acute glaucoma; Pleural abscess cured by incision and drainage, 338—Tuberculosis; Fæcal fistula; Compound dislocation of astragalus; Coca and its alkaloid, 896

MEDICAL OFFICERS OF HEALTH SOCIETY.—The status of the medical officer of health as a criterion of sanitary progress, 169—Small-[illegible] their influence on surrounding [illegible] of disinfectants on [illegible]

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—Rules for the prevention of infectious and contagious diseases in schools, 61—Comma bacilli of Koch, Finkler, and Prior; Aphasia without lesion of Broca's convolution, 111—Eyesight in schools, 802

MEDICAL SOCIETY OF LONDON.—Trephining for depressed fracture; Statistics of cancer of the tongue, 207—Discussion on renal surgery, 295—Total amputation of the penis; Progressive anæmia; Cases of paralysis agitans; Necrosis of labyrinth, 345—Electric illumination of the various cavities of the human body, 385—Annual general meeting; Diet in the febrile state, 433—Remarks from the president; Ipecacuanha in dysentery; *Infective endocarditis (mycosis endocardii)*, 476—Constitutional treatment of diseases of the uterus and its [illegible] after gangrene of [illegible] ments of long [illegible] of cervical caries, [illegible] and mucous polypi; The larynx in tabes dorsalis, 619—Myxœdema; *Uncomplicated brachial monoplegia from lesion of internal capsule*, 709—*Treatment of gangrenous intestine in* strangulated hernia, 759—Syphilitic disease of the brain; Treatment of cancer of the cervix uteri, 846

MIDLAND MEDICAL SOCIETY.—Ligature of the common carotid artery for hæmorrhage from the external auditory meatus, 316—General paralysis of the insane; General summary of conclusions from 1000 cases of abdominal section, 316—Inversion of the uterus; Muscular atrophy due to lead, 388—The social aspect of imbecility and insanity—Strangulated congenital *hernia*; *Absence of iris in* both eyes, 478—Angular ankylosis of wrist; Squibb's apparatus for the estimation of urea; Concomitant and internal strabismus, 568—Spinal meningitis, 641—Necrosis of radius; Pachymeningitis cervicalis hypertrophica; Perforating ulcer of foot; Intra-cranial hydatid; Germ theory of phthisis, 802—Locomotor ataxy with joint disease; Thyrotomy for papilloma of the larynx; Collection of calculi, 1038

OBSTETRICAL SOCIETY.—Exhibition of specimens; Extirpation of the uterus, 207—Prevention of ophthalmia neonatorum and its ravages, 315—Extirpation of the uterus for cancer, 521—Sequel to a case of ovariotomy; Circulation in the uterus; Absence of uterus and *occlusion of vagina*, 751—*Ulceration of* lupus of the female generative organs, including perforations, pits, and excavations; Uterine fibroid complicating labour and treated by enucleation, 939—*Serous perimetritis*; pseudo-osteomalacic pelvis of Naegele, 1166

OPHTHALMOLOGICAL SOCIETY.—Influence of *vapours of bisulphide of carbon and of chloride* of sulphur on the vision and general health; Cocainised eye; New ophthalmoscope, 112—Prevention of blindness from ophthalmia neonatorum; Nævus of choroid; Favus of the upper eyelid; Tuberculosis of cornea; Evisceration of the globe of the eye, 566—Ciliary nerves in certain diseases of the eye; Spontaneous disappearance of diabetic cataract; Nævus of choroid; Reflex ophthalmitis; Periodic paralysis of third nerve; Coloboma; Rupture of eyeball, 938—Congenital changes in vitreous body; "Black" cataract; *Nævoid conditions of eyelids and* orbital tissues; Intraocular gumma; Double retinal glioma, 1084

PATHOLOGICAL SOCIETY.—Fracture of the first rib; Simple fracture of skull in infants, followed by pulsating tumour, 62—Malignant disease of spermatic cord; *Congenital disease* of heart; Synostosis of dorsal vertebræ; Tubular epithelioma of upper jaw; Suppuration in joints in congenital syphilis, 157—Cancer in a cirrhotic liver and adrenals, [illegible] skin and viscera; [illegible] Addison's disease; [illegible] *and adrenals of* an infant; Addison's disease; Tumours of pituitary body; Hypertrophic cirrhosis and congenital disease of kidneys, 251—New growths in intestines; Spondylolisthesis and other results of pressure on the spinal column; Lung disease in wild animals; Sudden death *from impaction of trachea by* a bronchial gland; Malignant growth in the *forearm of an infant*; *Renal cancer associated* with calculi, 340—Rhino-scleroma; Sarcomata of bladder; Congenital obstruction of intestine; Adeno-sarcoma of pineal body; Fractures of hyoid bone and larynx; Tubercular pyo-salpinx; *Peculiar form of* nephritis, 423—Aneurysm of splenic artery rupturing into stomach; Congenital deformity; *Osteitis deformans*; *Synovial cysts* in connexion with joint disease; Primary sarcoma of penis; Dislocated hip; Fatal hæmoptysis from hydatid of lung, 518—Violet *pigment discharged from the mouth*; *Atrophy of the liver*; *Rupture of aorta*; Deposit of bone in testis; Thrombosis of vena cava and primary sarcoma of adrenal; Congenital sarcoma of testis; "Red-water," 662—Displacement of lumbar vertebræ; Cerebral arteries in states of congestion; Hypospadias; Destructive disease of lung; Acute ulceration of colon; Cyst growing from wall of intestine; C[illegible] 748—Tumour of brain; [illegible] child; Sarcom[illegible] carcinoma [illegible] us of tibia and fibula; Chronic cerebro-spinal *meningitis*; *Actinomycosis*; *Typhoid fever in* animals, 844—Varicella gangrenosa; Thrombosis of veins from gonorrhœa; Addison's disease; Atrophy of adrenals; Rodent ulcer; Secondary glioma; Calculus in both ureters, 987

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Discussion on the tubercle bacillus and on the pathology of phthisis, 107, 155—Perforation of the mastoid cells; Simultaneous double distal ligature for innominate aneurysm, 201—Displacement and fracture of the axis; The radical cure of club-foot, 294—Hereditary *locomotor ataxy*; Fatal hæmoptysis, 383—Annual general meeting; President's address, 428—The treatment of acute peritonitis by abdominal section, 475—Discussion on cholera, 563, 615—Aneurysm of abdominal aorta treated by distal compression; Localisation of motor centres in spinal cord, 705—Non-ovarian dermoid tumours; Pathological histology *of semilunar and superior cervical* sympathetic ganglia, 758—Excision of cerebral tumour, 801—Hæmaturia from Bilharzia hæmatobia; Experimental production of chorea, 983—Fatty tumours; Lympho-sarcoma of tongue, 1053

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Aortic disease; Cardiac disease; Tumour of the brain; Urticaria, 17—Cocaine as a local anæsthetic; Cystic sarcoma of tibia; Congenital coccygeal tumour; Stricture of pylorus; Sci[illegible] liver; In[illegible] hernia; [illegible] drainage in otorrhœa; Hydatid disease of liver and spleen; Cephalalgia; Treatment of empyema, 337—Perihepatitis; Charcot's disease; Thoracic aneurysm; Enlarged heads; Fracture of cervical vertebra, 665—Leucocythæmia; Aortic stenosis; Epilepsy, 755—Pneumothorax; Enlarged spleen; Implication of the *mastoid process* in ear disease; Atheroma of heart; Hæmoglobinuria, 1038—Hysterectomy; Pseudo-hypertrophic paralysis; Leucocythæmia, 1088

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Sewage disposal, 817

WEST HERTS MEDICAL ASSOCIATION.—Cause and method of propagation of cholera, 803

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Sympathetic ophthalmia; Uses of sulphide of calcium; Inflammation, abscess, and new growths of the ethmoid cells, 63—Peritoneal abscess following attacks of enteric fever; Hemiplegia in a child, 992

WOLVERHAMPTON DISTRICT MEDICAL SOCIETY.—Cheap and ready way of treating club-foot; Value of cocaine as a local anæsthetic for operations on the eye, 100—Puerperal fever, 208—Radical cure of inguinal hernia; Epithelial cancer of tongue; Puerperal fever, 569—Climacteric disorder, 663

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—Germ theory of disease, 207

Medicine in art, 24

Mind and matter reconciled, 1007
Minns, Mr. A., on cases of carbuncle in railwa porters, 323

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

BIRMINGHAM GENERAL HOSPITAL.—Subspinous dislocation of the humerus, 11

BOURNEMOUTH COTTAGE HOSPITAL.—A case bullet wound of the skull; recovery, 61; Sequel to the case of bullet wound of t skull; necropsy, 151 [illegible] General Hospital.—Cases of aneurysm in the lower extremity treated by digital compression, 953

Charing-Cross Hospital.—Case of late congenital syphilis of the throat; treatment with mercury and rectal alimentation; cure; remarks, 615—Traumatic aneurysm of the ulnar artery; operation; recovery, 796—Popliteal aneurysm; operation; cure, 1033

City of London Infirmary.—Carcinoma of liver, with great contraction of stomach necropsy, 747

[illegible] Royal Infirmary.—Malignant endocarditis following a slight injury to the knee; death within fourteen hours of admission; necropsy, 1165

Dunedin Hospital, New Zealand.—A case of nephrectomy for calculous pyelitis and pyonephrosis; cure, 1051

[illegible]ch Hospital.—Dislocation of forearm of eight weeks' standing; reduction, 705

[illegible]ock Infirmary.—Penetrating wound of abdomen, with protrusion of stomach and intestines; reduction of hernia after enlargement of wound; death, 1083

Guy's Hospital.—Eight cases of cataract operations in aged patients, cure, 249—Distension of frontal sinus treated by incision and drainage; cure, 819—Surgical cases, 953

Halifax Union Infirmary.—A case of Cæsarean section; death; autopsy, 155

Hospital for Epilepsy and Paralysis, Regent's-park.—Sequel to the case of excision of a tumour from the brain, 13

[illegible] Station Hospital.—Enlargement of the bursa beneath the semi-membranosus after injury; suppuration extending to the knee-joint; aspiration; amputation; recovery, 427

Kensington Infirmary.—Ovariotomy, with recovery, 1125

Kidderminster Infirmary.—Compound depressed fracture of skull; exudation of cerebral matter; trephining; recovery, 294

King's College Hospital.—Simple depressed fracture of skull; trephining; recovery, 202—Embolism of right middle cerebral artery simultaneously with embolism of right brachial; gangrene of right thumb and little finger; recovery, 1125

[illegible] Fever Hospital.—Death after the use of antipyrin; necropsy; remarks, 382

Leeds General Infirmary.—Two cases of fracture of the astragalus, and a case of separation of the upper epiphysis of the radius, [illegible]

[illegible] Union Infirmary.—Three cases, with post-mortem examination, illustrating some points in cerebral localisation of function, [illegible]

Leicester Infirmary and Fever House.—Acute hydrocele; pleurisy and pericarditis; death; necropsy, 748—Strangulated femoral hernia without constipation; death; necropsy, 981

Leith Hospital.—Compound depressed fracture of the skull; exudation of cerebral matter; recovery, 283

Liverpool Royal Infirmary.—Case of compound dislocation of the elbow-joint, with division of the main artery and vein, healed, with restoration of all movements; remarks, [illegible]—Dislocation of shoulder; reduction followed by aneurysm; treated successfully by ligature of subclavian, 704—Suicidal wound of neck treated by tracheotomy and the insertion of deep sutures, 842—Cases of abdominal section; convalescent, 1035

London Hospital.—Transverse fracture of patella; aspiration of joint; suppuration; antiseptic incisions into joint; wiring of fragments; recovery, 153

Manchester Royal Infirmary.—Two cases of spinal injury, 333—Coexisting renal and biliary calculi; cholecystotomy; death; necropsy; remarks, 563

Middlesex Hospital.—A very large uterine fibro-myoma, together with the uterus, its appendages, and both ovaries, successfully removed by abdominal section, 562—Strangulated femoral hernia; operation; recovery, [illegible]—Strangulated umbilical hernia; operation; removal of sac; recovery, ib.

Newcastle-on-Tyne Infirmary.—Wound of the cornea, with prolapse of the iris; removal of foreign bodies from the orbit; cure, 155—Primary sarcoma of the retro-peritoneal glands; death; necropsy; remarks, 937

Nottingham Hospital for Women.—Syphilitic stricture and ulceration of the rectum; colotomy; recovery, 292—Extra-peritoneal hæmatocele; rectal constriction; colotomy; recovery, 293.—Sarcoma of scapula; excision of the tumour and portion of bone involved in the growth; recovery, with useful arm, ib.

Nottingham Children's Hospital.—A case of meningocele; operation; death; necropsy; remarks, 890
